HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
A MEMORY GRADIENT ALGORITHM FOR $\ell_2 - \ell_0$ REGULARIZATION WITH APPLICATIONS TO IMAGE RESTORATION

ABSTRACT

In this work, we consider a wide range of inverse problems where an image $\hat{x} \in \mathbb{R}^N$ can be efficiently estimated from degraded data $y \in \mathbb{R}^Q$ by using a class of sparsity promoting regularized criteria. In many computed imaging applications, the observations are related to the original image $x$ through a linear model of the form $y = Hx + u$, where $H$ is a matrix in $\mathbb{R}^{Q \times N}$ that models the degradation process (e.g., a convolution operator) and $u$ is an additive noise vector. A usual approach is to recover $x$ by solving the following penalized optimization problem:

$$\min_{x \in \mathbb{R}^N} \left( F_\delta(x) = \Phi(Hx - y) + \Psi_\delta(x) \right), \quad (1)$$

which combines a data-fidelity term $\Phi$ and a regularization term $\Psi_\delta$ parameterized by a constant $\delta > 0$. In this work, we will be interested in the case when $\Phi$ is a function with a Lipschitz continuous gradient. An important particular case is when $\Phi$ is the squared Euclidean norm. The problem then reduces to a penalized least squares (PLS) problem [1]. Another case of interest is when $\Phi$ is the separable Huber function [2, Example 5.4] which is useful to limit the influence of outliers in the observed data.

An efficient strategy to promote images formed by smooth regions separated by sharp edges, is to use regularized terms of the form

$$\Psi_\delta(x) = \lambda \sum_{c=1}^{C} \psi_\delta(V_c^T x) + \|\Pi x\|^2, \quad (2)$$

where $V = \{ V_c, c \in \{1, \ldots, C\} \}$ is a dictionary of analysis vectors in $\mathbb{R}^N$, $\lambda > 0$ is a weighting factor and $\Pi$ is a matrix in $\mathbb{R}^{P \times N}$. For edge preserving purposes, $V_c$ may be a vector serving to compute a discrete difference between neighboring pixels. The final quadratic penalty term in (2) may play an important role similar to the elastic net regularization introduced in [3].

We seek to establish some of the theoretical properties of this framework.

In order to preserve significant coefficients in $V$, $\psi_\delta$ should have a slower than parabolic growth, as this reduces the cost associated with these components. Two of the main families of such functions known in the literature are:

- $\ell_2 - \ell_1$ functions, i.e. convex, continuously differentiable, asymptotically linear functions with a quadratic behavior near 0. A typical example is the hyperbolic function $(\forall t \in \mathbb{R}) \psi_\delta(t) = \sqrt{t^2 + \delta^2}, \delta > 0$. In the limit case when $\delta \to 0$, the classical $\ell_1$ norm is obtained.

- $\ell_2 - \ell_0$ functions, i.e. asymptotically constant functions with a quadratic behavior near 0. A typical example is the truncated quadratic function $(\forall t \in \mathbb{R}) \psi_\delta(t) = \delta^{-2} \min(t^2, \delta^2), \delta > 0$. When $\delta \to 0$, the $\ell_0$ penalty is obtained.

The $\ell_2 - \ell_0$ approach is popular in the literature [4, 5, 6], due to its ability to better preserve edges within homogeneous regions. However, the non-convexity and sometimes non-differentiability of the potential function lead to a difficult optimization problem.

Here, we will consider a class of differentiable potential functions, which can be viewed as smoothed versions of the truncated quadratic penalization. The rest of the paper is organized as follows: properties of the considered optimization
problem are first investigated in Section 2. Then, we introduce in Section 3 an original minimization strategy based on a memory gradient scheme. We also discuss the general convergence properties of our algorithm. Finally, Section 4 illustrates the good performance of the algorithm through a set of comparisons and experiments in image restoration.

2. CONSIDERED CLASS OF CRITERIA

We will focus on potentials satisfying the following properties:

**Assumption 1.**

(i) \((\forall \delta \in (0, +\infty)) \psi_\delta \text{ is differentiable.}\)

(ii) \((\forall (\delta_1, \delta_2) \in (0, +\infty)^2) \delta_1 \leq \delta_2 \Rightarrow (\forall t \in \mathbb{R}) \psi_{\delta_1}(t) \geq \psi_{\delta_2}(t) \geq 0.\)

(iii) \((\forall t \in \mathbb{R}) \lim_{\delta \to 0} \psi_\delta(t) = \begin{cases} 0 & \text{if } t = 0 \\ 1 & \text{otherwise.} \end{cases}\)

The latter property shows that the \(\ell_0\) penalty is asymptotically obtained. Examples of functions satisfying the above assumptions are the following

- \((\forall t \in \mathbb{R}) \psi_\delta^{(1)}(t) = \frac{t^2}{2\delta^2 + t^2}\)
- \((\forall t \in \mathbb{R}) \psi_\delta^{(2)}(t) = 1 - \exp(-\frac{t^2}{2\delta^2})\)

which can be viewed as smoothed versions of the truncated quadratic function (see Fig. 1).

![Fig. 1. Truncated quadratic penalty (black, full) and its smoothed approximations \(\psi_\delta^{(1)}\) (red, dashed) and \(\psi_\delta^{(2)}\) (blue, dash-dot).](image)

We have then the following result:

**Proposition 1.** Assume that \(\Phi\) in (1) is coercive (that is \(\lim_{\|x\| \to +\infty} \Phi(x) = +\infty\)) and that \(\text{Ker } H \cap \text{Ker } \Pi = \{0\}\), where \(\text{Ker } H\) and \(\text{Ker } \Pi\) are the nullspaces of \(H\) and \(\Pi\), respectively. Then, for every \(\delta > 0\), \(F_\delta\) has a minimizer.

Note that, in the particular case when \(H\) is injective (e.g. in denoising applications), the existence of a minimizer is ensured if \(\Pi = 0\). Asymptotic convergence can also be obtained by using epi-convergence of \(F_\delta\) to the following \(\ell_0\)-penalized objective function:

\[
F_0: x \mapsto \Phi(Hx - y) + \lambda \ell_0(Vx) + \|\Pi x\|^2,
\]

where \(V^T = [V_1 \ldots V_C]\).

**Proposition 2.** Let \((\delta_n)_{n \in \mathbb{N}}\) be a decreasing sequence of positive real numbers converging to 0. Under the same assumptions as in Proposition 1, \(\inf F_{\delta_n} \to \inf F_0\) as \(n \to +\infty\). In addition, if for every \(n \in \mathbb{N}\) \(\bar{\delta}_n\) is a minimizer of \(F_{\delta_n}\), then the sequence \((\bar{\delta}_n)_{n \in \mathbb{N}}\) is bounded and all its cluster points are minimizers of \(F_0\).

The above proposition justifies theoretically that a minimizer of \(F_0\) can be well-approximated by choosing a small enough \(\delta\).

3. PROPOSED OPTIMIZATION ALGORITHM

3.1. Memory gradient algorithm

A classical optimization strategy consists of building a sequence \((x_k)_{k \in \mathbb{N}}\) of \(\mathbb{R}^N\) in order to iteratively decrease the criterion \(F_\delta\). This can be performed by moving the current solution \(x_k\) at iteration \(k \in \mathbb{N}\) along a direction \(d_k \in \mathbb{R}^N\):

\[
x_{k+1} = x_k + \alpha_k d_k,
\]

where \(\alpha_k > 0\) is the stepsize and \(d_k\) is a descent direction i.e., it satisfies \(g_k^T d_k < 0\) where \(g_k\) denotes the gradient of \(F_\delta\) at \(x_k\).

The simplest choice for the direction is the opposite of the gradient of the criterion at the current point, which leads to the steepest descent algorithm. A significant improvement of the convergence rate is achieved by the nonlinear conjugate gradient (NLCG) algorithm, where the direction results from a linear combination of the opposite gradient with the previous direction:

\[
d_k = -g_k + \beta_k d_{k-1}.
\]

One of the central points in the development of NLCG methods is to define a suitable value of \(\beta_k\) based on certain conjugacy principles [7]. In the memory gradient (MG) method introduced in [8], the optimization scheme (4)-(5) is reformulated as:

\[
x_{k+1} = x_k + D_k s_k,
\]

where \(D_k = [-g_k \quad x_k - x_{k-1}] \in \mathbb{R}^{N \times 2}\) denotes a set of search directions and \(s_k \in \mathbb{R}^2\) a multivariate stepsize that aims at partially minimizing \(f_\delta: s \mapsto F_\delta(x_k + D_k s)\).

Recently, the MG scheme (6) has been shown to outperform standard descent algorithms such as NLCG over a set of PLS minimization problems [9, 10]. The convergence of the recursive update equation (6) requires the design of a proper strategy to determine the stepsize \(s_k\), which we discuss in the next section.

3.2. Majorize-Minimize stepsize

The minimization of \(f_\delta\) using the Majorization-Minimization (MM) principle is performed by successive minimizations of
tangent majorant functions for \( f_\delta \). A function \( q(., s') \) is said to be a tangent majorant for \( f_\delta \) at \( s' \) if for all \( s \),

\[
q(s, s') \geq f_\delta(s) \quad \text{and} \quad q(s', s') = f_\delta(s').
\]

Following [9], we propose the quadratic tangent majorant function of the form:

\[
q(s, s') = f_\delta(s') + \nabla f_\delta(s')^\top (s-s') + \frac{1}{2} (s-s')^\top B_\delta(s-s'),
\]

where \( B_\delta \) is a \( 2 \times 2 \) symmetric positive definite matrix that ensures the fulfillment of majorization properties (7). The initial minimization of \( f_\delta \) is replaced by a sequence of easier subproblems, corresponding to the MM update rule:

\[
\begin{cases}
  s_k^0 = 0, \\
  s_k^j = \arg \min_s q(s, s_k^{j-1}), \quad j \in \{1, \ldots, J\}, \\
  s_k = s_k^J.
\end{cases}
\]

Let us now make the following additional assumptions:

**Assumption 2.**

(i) The gradient of \( \Phi \) is \( L \)-Lipschitzian,\(^1\)

(ii) \( \psi_\delta \) is even.

(iii) \( \psi_\delta(\sqrt{\tau}) \) is concave on \( \mathbb{R}^+ \).

(iv) There exists \( \omega \in [0, +\infty) \) such that \( \forall t \in (0, +\infty) \)

\[
0 \leq \psi_\delta(t) \leq \omega(t) \quad \text{where} \quad \psi_\delta \quad \text{is the derivative of} \quad \psi_\delta. \quad \text{In addition,} \lim_{t \to 0} \psi_\delta(t)/t \in \mathbb{R}.
\]

We emphasize the fact that Assumptions 2(ii)-(iv) hold for the \( t_2-t_0 \) penalties \( \psi_\delta^{(1)} \) and \( \psi_\delta^{(2)} \). Let us also introduce

\[
A(x) = \mu H^\top H + 2\Pi^\top \Pi + \lambda V^\top \text{Diag} \{b(x)\} V,
\]

where \( \mu \in (L, +\infty) \) and \( b(x) \) is a \( C \) dimensional vector with entries: \( \forall c \in \{1, \ldots, C\} \) \( b_c(x) = \omega_\delta(V_c^\top x) \), where \( \forall t \in \mathbb{R} \) \( \omega_\delta(t) = \psi_\delta(t)/t \) (the function \( \omega_\delta \) is extended by continuity at 0). According to [11], taking

\[
B_{s_k} = D_k^\top A(x_k + D_k s_k^j) D_k
\]

ensures that \( q(., s_k^j) \) is a tangent majorant for \( f_\delta \) at \( s_k^j \). Hence, given (8), we obtain an explicit stepsize formula:

\[
s_k^{j+1} = s_k^j - B_{s_k}^{-1} \nabla f_\delta(s_k^j).
\]

\[\]

\[\]

3.3. Convergence result

**Proposition 3.** Under the same assumptions as in Proposition 1, for all \( J \geq 1 \), the MM-MG algorithm given by (6) and (9) converges in the sense that \( \lim_{k \to \infty} g_k = 0 \). Furthermore, under some technical assumptions, it can be proved that the sequence \( x_k \) converges to a critical point \( \bar{x} \) of \( F_\delta \).

Note that the computation of the MM stepsize requires specifying the number of MM sub-iterations \( J \). In our experiments, \( J = 1 \) was observed to yield the best results in terms of convergence profile.

4. APPLICATION TO EDGE-PRESERVING IMAGE RESTORATION

Two image restoration scenarios are considered. In the first one, \( y \) is a noisy, blurred image generated by using a Gaussian point spread function of standard deviation 2.24 and of size \( 17 \times 17 \), with the convolution product implemented using the Dirichlet boundary condition. In the second case, only noise is added to the original image. In both cases, the noise is white additive Gaussian with standard deviation \( \sigma_u \), and the original image is the standard Elaine image of size \( N = 512 \times 512 \). An analysis-based PLS criterion is considered by taking \( \Phi = \| \cdot \|^2 \) and \( \Pi = \tau I \) with \( \tau \in \mathbb{R} \) in (1) and (2). In our experiments, \( V \) is simply the first-order difference matrix (i.e. the discrete gradient computed in the horizontal and vertical directions), \( \psi_\delta = \psi_\delta^{(2)} \), and \( H \) is the blur operator or the identity matrix respectively. This criterion depends on the parameters \( \lambda, \delta \) and \( \tau \). With deblurring applications, the convolution matrix \( H \) is not necessarily injective. Thus, we set \( \tau \) equal to a small positive value in order to fulfill the assumptions of Propositions 1-3. In the denoising case, \( \tau \) is set to zero. Parameters \( \lambda \) and \( \delta \) are tuned to maximize the SNR between the original image \( \bar{x} \) and its reconstructed version \( x \). In Figs. 2 and 3, the reconstructed images and their SNR, MSSIM [12] are displayed. They were obtained with the MM-MG algorithm initialized with a uniform zero image.

Table 1 shows the computational times achieved with several optimization strategies applied to the denoising problem. These results were obtained with C codes running on a single-core Intel Xeon 2.5GHz with 32GB of RAM (RedHat Enterprise Linux 5.5). First, we compare the MM-MG algorithm given by (6) and (9) where \( J = 1 \), with the Beck-Teboulle (BT) gradient-based algorithm [13] and with the fast version of half quadratic (HQ) algorithm [11]. In the latter, the inner optimization problems are solved partially with a conjugate gradient algorithm. For each algorithm, the global stopping rule is \( \| g_k \|/\sqrt{N} < 10^{-4} \). For this setting, no significant differences between algorithms have been observed in terms of reconstruction quality. According to Table 1, our method outperforms both BT and HQ algorithms in terms of convergence speed. Similar conclusions can be drawn for the deconvolution problem (MM-MG: 11 s, BT: 30 s, HQ: 35 s).

\[^1\] This means that \( \forall x \in \mathbb{R}^N, \forall y \in \mathbb{R}^N \) \( \| \nabla \Phi(x) - \nabla \Phi(y) \| \leq L \| x - y \| \).
In this work, we have considered image restoration problems with non-convex $\ell_2 - \ell_0$ regularization terms. These penalties are similar in principle to truncated quadratic terms that are widely used in combinatorial optimization methods, but are regular enough to allow us to propose an efficient and effective Majorization-Minimization Memory Gradient algorithm. In an image denoising application, we showed that our approach obtains almost identical results as state-of-the-art optimization strategies but outperforms them significantly in term of speed. In addition, our framework appears also to be quite competitive for deblurring.
