# Non-intrusive estimation of loss resistance of planar antenna over human body

T. Alves, B. Poussot and J.-M. Laheurte

A new method is presented to estimate the loss resistance of antennas located slightly above a lossy medium. This technique is more specifically developed for the context of body area networks. This method is based on the estimation of the antenna resistance above the medium and above a perfect electric conductor.

**Introduction:** The ‘Wheeler cap method’ [1] is the most commonly used method to estimate the efficiency of small antennas. This consists in enclosing the antenna with a metallic box that is large enough to not disturb the reactive near field and cancel the antenna radiation (typically cap dimensions should be greater than  $\lambda/2\pi$ ). The antenna efficiency is then calculated from the knowledge of the antenna impedance with and without the Wheeler cap.

However, in the presence of any lossy medium, the induced currents into it can be seen as an extension of the antenna body [2]. As a result, the total reactive field is contained in a nearly  $\lambda/2$  diameter sphere [3] which, in turn, involves a bigger Wheeler cap.

In the context of body area networks (BANs), antennas are in the vicinity of the body, a lossy medium whose composition [4, 5] may largely vary. In [6], the Wheeler cap method was applied to BAN antennas with small ground planes partially including the phantom inside the cap. Other authors have introduced the ‘body-worn efficiency’ [7] which is the ratio of the in-body ‘radiated power’ to the free space radiated power.

The methods described above either require a field measurement inside a body phantom or an unpractical Wheeler cap overlapping body tissues. This Letter proposes a simple method based on the compensation theorem to estimate the loss resistance of BAN antennas. From the simulated or measured values of the input resistance of the antenna, first above the body tissues, then above a metallic ground plane, it is possible to extract the loss resistance above the body tissues. Knowing the loss resistance  $R_L$  and the total input resistance  $R_{in}$ , it is further possible to deduce the antenna efficiency  $\eta = 1 - R_L/R_{in}$  in the presence of the body.

**Compensation theorem:** The compensation theorem applied in electromagnetics was first demonstrated by Montearth [8]. It gives the impedance variation  $\Delta Z$  between the impedance  $Z$  of the antenna located above a lossy medium and the impedance  $Z_{PEC}$  of the same antenna located above a perfect electric conductor (PEC) [9, 10]

$$\Delta Z = Z - Z_{PEC} = \frac{1}{I_0^2} \int_S H_{//}^2 Z_s dS \quad (1)$$

- $Z_s$ : surface impedance modelling of the lossy medium
- $Z$ : impedance of the antenna over the lossy medium
- $Z_{PEC}$ : impedance of the antenna above a PEC
- $\Delta Z$ : impedance increment
- $H_{//}$ : tangential magnetic field over a PEC
- $I_0$ : root-mean-square current value at the antenna feeding point
- $S$ : boundary surface exhibiting a surface impedance  $Z_s$ .

**Power considerations:** Comparing the power delivered to the antenna over a PEC and over a lossy medium, we exploit (1) to show that an antenna over a lossy medium consumes an additional power that is

$$\Delta P = \Re\{\Delta Z\} I_0^2 = \Re\left\{ \int_S H_{//}^2 Z_s dS \right\} \quad (2a)$$

This leads to an increment of power given by

$$\Delta P = \int_S |H_{//}|^2 |Z_s| \cos(\varphi_s + 2\varphi_h) dS \quad (2b)$$

where  $\varphi_s$  is the phase of the surface impedance and  $\varphi_h$  is the phase of the tangential magnetic field. On the other hand, the power  $P_L$  absorbed by any lossy medium is given by the well-known formula

$$P_L = \int_S |H_{//}|^2 |Z_s| \cos \varphi_s dS \quad (3)$$

From (2b) and (3), it is clear that  $P_L$  and  $\Delta P$  are equal when  $\varphi_h$  is small. This is verified when the antenna is close to the medium [9, 10]. Therefore, we conclude that when an antenna is close to a lossy medium, the additional consumed power is mainly due to the medium losses. Under this condition, the loss resistance  $R_L$  of the antenna is given by

$$R_L \simeq \Re\{\Delta Z\} \quad (4)$$

The method presented in this Letter is based on this assumption.

**Estimation of loss resistance:** To control the validity of (4), we compare the  $R_L$  values determined by two methods:

a.  $R_L$  determined from (4) and 4NEC2 simulations [11]:

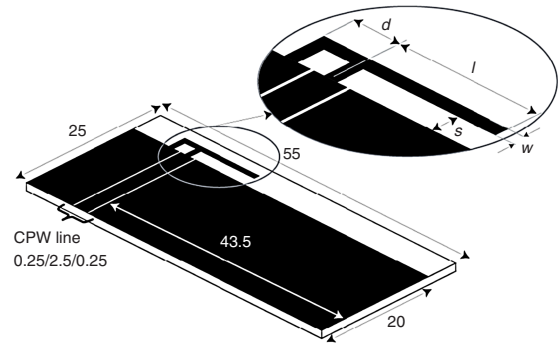

- Computation of the antenna impedance  $Z$  over a lossy medium
- Computation of the antenna impedance  $Z_{PEC}$  over a PEC
- Use of (4):  $\Re\{\Delta Z\} = \Re\{Z - Z_{PEC}\} = R_L$ .

It is important to note that this method can also be applied experimentally.

b.  $R_L$  determined from the following relation using the HFSS calculations of the antenna impedance  $Z$  and the efficiency  $\eta$  in the presence of a lossy medium:

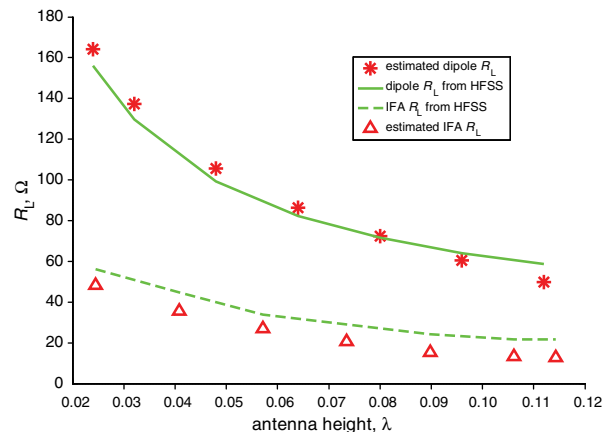

$$R_L = \Re\{Z\}(1 - \eta) \quad (5)$$

The comparison between these methods is realised at 2.4 GHz for a half-wavelength horizontal dipole (radius =  $\lambda_0/250$  and metallisation = PEC) and the integrated inverted-F antenna (IIFA) depicted in Fig. 1. The medium characteristics of the semi-infinite lossy medium used in the HFSS simulations are those of an available homogeneous torso phantom. The phantom relative permittivity and loss tangent ( $\epsilon_r = 27$  and  $\tan \delta = 0.505$ ) are extracted from measurements based on the open-ended coaxial probe technique.

**Fig. 1** Details of IIFA

Dimensions:  $w = 1$  mm,  $s = 2$  mm,  $l = 10.5$  mm,  $d = 3.5$  mm  
FR4 substrate ( $\epsilon_r = 4.4$ ,  $\tan \delta = 0.02$ ); thickness = 1.6 mm

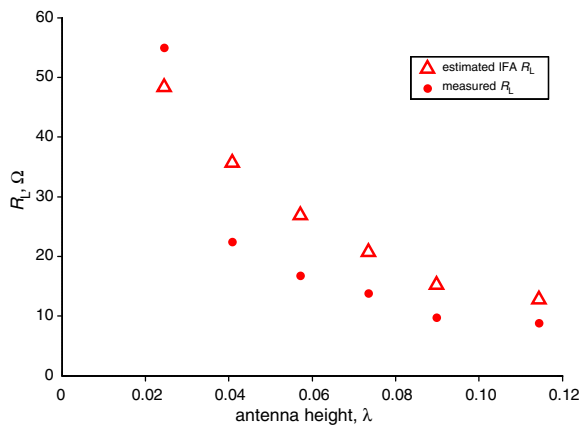

**Fig. 2** Loss resistance of half-wavelength dipole and IIFA

Comparison between two methods

The loss resistance is given for both antennas in Fig. 2 as a function of the normalised height  $h/\lambda_0$  above the medium interface. A good

agreement is observed between the two methods. However, it must be stressed that the relative differences are 2 and 8% for  $h = \lambda_0/40$ , and 17 and 25% for  $h = \lambda_0/10$  with the IIFA and the dipole, respectively. This increasing divergence for larger heights flows from the approximations in (4) that are not valid for large  $h/\lambda_0$ , i.e. the phase of the tangential magnetic field is no longer negligible on the body surface in the vicinity of the antenna. We conclude that the  $R_L$  estimation based on the compensation theorem is valid in the body context as long as the height above the interface is lower than  $\lambda_0/10$ , approximately (1.25 cm at 2.4 GHz), which is sufficient in most BAN scenarios.

Measurements are realised with the IIFA, first on the torso phantom, then on a large copper plate. Special care is taken to avoid cable radiations from the flow of external current with baluns made of a pair of  $\lambda/4$  stubs. Tunable plastic spacers are used to fix the antenna heights above the phantom surface.  $R_L$  is then deduced from the procedure described above and compared with the value obtained with the same procedure using the HFSS impedance values. In Fig. 3, the  $R_L$  curves follow the same trend. Discrepancies can be attributed to the difficulty in measuring the correct impedance in small antennas where the antenna body extends partially to the cable and the balun structure. In addition, the presence of the antenna connector and cable in the vicinity of the interface perturbs the measurements.

Comparison of experimental and simulated results

**Conclusion:** A new technique has been described to estimate the loss resistance of an antenna close to a lossy interface. The method is

based on the knowledge of the antenna resistance above a lossy surface and above a PEC. It has been validated using two numerical-based estimations of  $R_L$ . It can also be applied experimentally by measuring the antenna resistance first above a lossy medium then above a metallic ground plane. A straightforward application is the BAN context, in which Wheeler caps are unpractical because they should include some volume of the body or phantom.
