HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
We study the convergence in distribution norms in the Central Limit Theorem for non identical distributed random variables that is

\[ \epsilon_n(f) := \mathbb{E}(f\left(\sum_{i=1}^{n} Z_i\right)) - \mathbb{E}(f(G)) \rightarrow 0 \]

where \( S_n = \sum_{i=1}^{n} Z_i \) with \( Z_i \) centred independent random variables (with a suitable re-normalization for \( S_n \)) and \( G \) is standard normal. We also consider local developments (Edgeworth expansion).

This kind of results is well understood in the case of smooth test functions \( f \). If one deals with measurable and bounded test functions (convergence in total variation distance), a well known theorem due to Prohorov shows that some regularity condition for the law of the random variables \( X_n, n \in \mathbb{N} \), on hand is needed. Essentially, one needs that the law of \( X_n \) is locally lower bounded by the Lebesgue measure (Doeblin’s condition). This topic is also widely discussed in the literature (see Battacharaya and Rao [12]). Our main contribution is to discuss convergence in distribution norms, that is to replace the test function \( f \) by some derivative \( \partial^\alpha f \) and to obtain upper bounds for \( \epsilon_n(\partial^\alpha f) \) in terms of the original function \( f \).

**Abstract**

We study the convergence in distribution norms in the Central Limit Theorem for non identical distributed random variables that is

\[ \epsilon_n(f) := \mathbb{E}(f\left(\sum_{i=1}^{n} Z_i\right)) - \mathbb{E}(f(G)) \rightarrow 0 \]

where \( S_n = \sum_{i=1}^{n} Z_i \) with \( Z_i \) centred independent random variables (with a suitable re-normalization for \( S_n \)) and \( G \) is standard normal. We also consider local developments (Edgeworth expansion).

This kind of results is well understood in the case of smooth test functions \( f \). If one deals with measurable and bounded test functions (convergence in total variation distance), a well known theorem due to Prohorov shows that some regularity condition for the law of the random variables \( X_n, n \in \mathbb{N} \), on hand is needed. Essentially, one needs that the law of \( X_n \) is locally lower bounded by the Lebesgue measure (Doeblin’s condition). This topic is also widely discussed in the literature (see Battacharaya and Rao [12]). Our main contribution is to discuss convergence in distribution norms, that is to replace the test function \( f \) by some derivative \( \partial^\alpha f \) and to obtain upper bounds for \( \epsilon_n(\partial^\alpha f) \) in terms of the original function \( f \).

1 Introduction

We consider a sequence of centred independent random variables $Z_k \in \mathbb{R}^d, k \in \mathbb{N}$ with covariance matrices $\sigma_{i,j}^k = \mathbb{E}(Z_i^k Z_j^k)$ and we look to

$$S_n(Z) = \sum_{k=1}^{n} Z_k.$$ (1.1)

Our aim is to obtain a Central Limit Theorem as well as Edgeworth developments in this framework. The basic hypotheses are the following. We assume the normalization condition

$$\sum_{k=1}^{n} \sigma_k = I_d$$ (1.2)

where $I_d \in M_{d\times d}$ is the identity matrix. Moreover we assume that for each $p \in \mathbb{N}$ there exists a constant $C_p \geq 1$ such that

$$\max_k \mathbb{E}(|Z_k|^p) \leq \frac{C_p(Z)}{n^{p/2}}.$$ (1.3)

Let $\|f\|_{k,\infty}$ denote the norm in $W^{k,\infty}$, that is the uniform norm of $f$ and of all its derivatives of order less or equal to $k$. First, we want to prove that

$$|\mathbb{E}(f(S_n(Z))) - \int_{\mathbb{R}^d} f(x) \gamma_d(x) dx| \leq \frac{C_0}{n^{1/2}} \|f\|_{3,\infty}$$ (1.4)

where $\gamma_d(x) = (2\pi)^{-d/2} \exp(-\frac{1}{2} |x|^2)$ is the density of the standard normal law. This corresponds to the Central Limit Theorem (hereafter CLT). Moreover we look for some functions (polynomials) $\psi_k : \mathbb{R}^d \to \mathbb{R}$ such that for $N \in \mathbb{N}$ and for every $f \in C_b^{(N+1)(N+3)}(\mathbb{R}^d)$

$$|\mathbb{E}(f(S_n(Z))) - \int_{\mathbb{R}^d} f(x) \left( \sum_{k=0}^{N} \frac{1}{n^{k/2}} \psi_k(x) \right) \gamma_d(x) dx| \leq \frac{C_N}{n^{(N+1)}} \|f\|_{(N+1)(N+3,\infty)}.$$ (1.5)

This is the Edgeworth development of order $N$. In the case of smooth test functions $f$ (as it is the case in (1.5)), this topic has been widely discussed and well understood: such development has been obtained by Sirazhdinov and Mamatov [21] in the case of identically distributed random variables and then by Götze and Hipp [16] in the non identically distributed case. A complete presentation of this topic may be found in the book of Battacharaya and Rao [12]. It it worth to mention that the classical approach used in the above papers is based on Fourier analysis. In particular, the coefficients $\psi_k$ in the above development are given as inverse Fourier transform of some suitable functions, so the expression of $\psi_k$ is not completely transparent and its explicit computation requires some effort.
In our paper we use a different approach based on the Lindemerg method for Markov semigroups (this is inspired from works concerning the parametrix method for Markov semigroups in [9]). This alternative approach is convenient for the proof of our main result concerning “distribution norms” (see below). But, even in the case of smooth test functions, this allows to obtain slightly more clear and precise results: we prove that $\psi_k$ are linear combinations of Hermite polynomials of order less or equal to $k$, whose coefficients are explicit and computed starting with the moments of $Z_i$ and $G_i$, $G_i$ denoting a Gaussian random variable with the same covariance matrix as $Z_i$. So the computation of these coefficients is easier. Moreover, our estimates hold for each fixed $n$ (in contrast with the ones in the above papers, which are just asymptotic).

A second problem is to obtain the estimate (1.5) for test functions $f$ which are not regular, in particular to replace $\|f\|_{(N+1)(N+3),\infty}$ by $\|f\|_\infty$. This amounts to estimate the error in total variation distance. In the case of identically distributed random variables, and for $N=0$ (so at the level of the standard CLT), this problem has been widely studied. First of all, one may prove the convergence in Kolmogorov distance, that is for $f=1_D$ where $D$ is a rectangle. Many refinements of this type of result has been obtained by Battacharaya and Rao and they are presented in [12]. But it turns out that one may not prove such a result for a general measurable set $D$ without assuming more regularity on the law of $Z_k$, $k \in \mathbb{N}$. Indeed, in his seminal paper [20] Prohorov proved that the convergence in total variation distance is equivalent to the fact that there exists $m$ such that the law of $Z_1 + \cdots + Z_m$ has an absolutely continuous component. In [3] Bally and Caramellino obtained (1.5) in total variation distance, for identically distributed random variables, under the hypothesis that the law of $Z_k$ is locally lower bounded by the Lebesgue measure. We assume this type of hypothesis in this paper also. More precisely we assume that there exists $r, \varepsilon > 0$ and there exists $z_k \in \mathbb{R}^d$ such that for every measurable set $A \subset B_r(z_k)$

$$\mathbb{P}(Z_k \in A) \geq \varepsilon \lambda(A)$$

(1.6)

where $\lambda$ is the Lebesgue measure. This condition is known in the literature as Doeblin’s condition. Under this hypothesis we are able to obtain (1.5) in total variation distance. It is clear that (1.6) is more restrictive than Prohorov’s condition. However we prove that in the framework of the CLT for identically distributed random variables, if we have Prohorov’s condition we may produce doubling condition as well, just working with the packages $Y_k = \sum_{i=2km+1}^{2(k+1)m} Z_i$. This allows us to prove Corollary 3.12 which is a stronger version of Prohorov’s theorem.

Let us finally mention another line of research which has been strongly developed in the last years: it consists in estimating the convergence in the CLT in entropy distance. This starts with the papers of Barron [11] and Johnson and Barron [14]. In these papers the case of identically distributed random variables is considered, but recently, in [8] Bobkov, Chistyakov and Götze obtained the estimate in entropy distance for the case of random variables which are no more identically distributed as well. We recall that the convergence in entropy distance implies the convergence in total variation distance, so such results are stronger. However, in order to work in entropy distance one has to assume that the law of $Z_k$ is absolutely continuous with respect to the Lebesgue measure and have finite entropy and this is more limiting than (1.6). So the hypothesis and the results are slightly different.

A third problem is to obtain the CLT and the Edgeworth development with the test function $f$ replaced by a derivative $\partial_\gamma f$. If the law of $S_n(Z)$ is absolutely continuous with respect to the Lebesgue measure, this means that we prove the convergence of the density and of its derivatives as well (which corresponds to the convergence in distribution norms). Unfortunately we fail to obtain such a result in the general framework: this is moral because we do not assume that the laws of $Z_k$, $k = 1, \ldots, n$ are absolutely continuous, and then the law of $S_n(Z)$ may have atoms. However we obtain a similar result, but we have to keep a “small error”. Let us give a precise statement of our result. For a function $f \in C^m_p(\mathbb{R}^d)$ ($m$ times differentiable with polynomial growth) we define $L_m(f)$ and $l_m(f)$ to
be two constants such that
\[
\sum_{0 \leq |\alpha| \leq m} |\partial_\alpha f(x)| \leq L_m(f)(1 + |x|)^{l_m(f)}.
\] (1.7)

Our main result is the following: for a fixed \( m \in \mathbb{N} \), there exist some constants \( C_N \geq 1 \geq c_N > 0 \) (depending on \( r, \varepsilon \) from (1.6) and on \( C_p \) from (1.3)) such that for every multi-index \( \gamma \) with \( |\gamma| = m \) and for every \( f \in C_p^m(\mathbb{R}^d) \)
\[
\left| \mathbb{E} \left( \partial_\gamma f(S_n(Z)) - \int_{\mathbb{R}^d} \partial_\gamma f(x) \left( \sum_{q=0}^{N} \frac{1}{n^{q/2}} \psi_q(x) \right) \gamma_d(x) dx \right) \right| \leq C_N \left( L_m(f)e^{-c_N \times n} + \frac{1}{n^2(N+1)} L_0(f) \right).
\] (1.8)

If the random variables \( Z_k, k \in \mathbb{N} \) are identically distributed we succeed to obtain exactly the same result under the Prohorov’s condition (see Corollary 3.12). So this is a strictly stronger version of Prohorov’s theorem (for \( m = 0 \) we get the convergence in total variation). Moreover, such result is used in [6] in order to give invariance principles concerning the variance of the number of zeros of trigonometric polynomials.

However we fail to get convergence in distribution norms because \( L_m(f)e^{-c_N \times n} \) appears in the upper bound of the error and \( L_m(f) \) depends on the derivatives of \( f \). But we are close to such a result: notice first that if \( f_n = f * \phi_{\delta_n} \) is a regularization by convolution with \( \delta_n = \exp(-\frac{c_n}{2} \times n) \) then (1.8) gives
\[
\left| \mathbb{E} \left( \partial_\gamma f_n(S_n(Z)) - \int_{\mathbb{R}^d} \partial_\gamma f_n(x) \left( \sum_{q=0}^{N} \frac{1}{n^{q/2}} \psi_q(x) \right) \gamma_d(x) dx \right) \right| \leq \frac{C_N}{n^2(N+1)} L_0(f). \] (1.9)

Another way to eliminate \( L_m(f)e^{-c_N \times n} \) is to assume that the law of \( Z_i, i = 1, ..., m \) are absolutely continuous with the derivative of the density belonging to \( L^1 \). This is done in Proposition 4.2 we prove that for every \( k \in \mathbb{N} \) and every multi-index \( \alpha \)
\[
\sup_x (1 + |x|)^2 |\partial_\alpha p_{S_n}(x) - \partial_\alpha \gamma(x)| \leq \frac{C}{\sqrt{n}}
\]
so, under these stronger conditions, we succeed to obtain convergence in distribution norms.

But the most interesting consequence of our result is given in Theorem 4.1 there we give an invariance principle for the occupation time of a random walk. More precisely we take \( \varepsilon_n = n^{-\frac{\beta}{2}(1-\rho)} \) with \( \rho \in (0, 1) \) and we prove that, for every \( \rho < \rho' \)
\[
\left| \sum_{k=1}^{n} \mathbb{E} \left( \frac{1}{\varepsilon_n} 1_{(-\varepsilon_n, \varepsilon_n)} \left( \sum_{i=1}^{k} Z_i \right) \right) - \mathbb{E} \left( \int_{0}^{1} \frac{1}{\varepsilon_n} 1_{(-\varepsilon_n, \varepsilon_n)} (W_s) ds \right) \right| \leq \frac{C}{n^2(1+\rho')}
\]
with \( W_s \) a Brownian motion (so \( \int_{0}^{1} \frac{1}{\varepsilon_n} 1_{(-\varepsilon_n, \varepsilon_n)} (W_s) ds \) converges to the local time of \( W \)). Here the test function is \( f_n = \frac{1}{\varepsilon_n} 1_{(-\varepsilon_n, \varepsilon_n)} \) and this converges to the Dirac function. This example shows that (1.8) is an appropriate estimate in order to deal with some singular problems.

The paper is organized as follows. In Section 2 we prove the result for smooth test functions (that is (1.5)) and in Section 3 we treat the case of measurable test functions. In order to do it we use some integration by parts technology which has already been used in [3] and which is presented in Section 3.1. We mention that a similar approach has been used by Nourdin and Poly [18], by using the \( \Gamma \)-calculus settled in [10]. The main result in Section 3 is Theorem 3.8. In Section 4 we treat
the two applications mentioned above. Finally we leave for Appendix A the explicit calculus of the coefficients $\psi_q$ from (1.5) for $q = 1, 2, 3$ and in Appendix B we prove a technical result which is used in our development.

Although many ideas in our paper come from previous works (mainly from Malliavin calculus), at the end we finish with an approach which is fairly simple and elementary - so we try to give here a presentation which is essentially self contained (even if some cumbersome and straightforward computations are just sketched).

2 Smooth test functions

2.1 Notation and main result

We fix $n \in \mathbb{N}$ and we consider $n$ centred and independent random variables $Z = (Z_k)_{1 \leq k \leq n}$ with $Z_k = (Z_k^1, \ldots, Z_k^d) \in \mathbb{R}^d$. We denote by $\sigma_k$ the covariance matrix of $Z_k$ that is

$$\sigma_{i,j}^k = \mathbb{E}(Z_i^k Z_j^k), \quad 1 \leq k \leq n.$$  

We look to

$$S_n(Z) = \sum_{k=1}^n Z_k.$$  

Our aim is to compare the law of $S_n(Z)$ with the law of $S_n(G)$ where $G = (G_k)_{1 \leq k \leq n}$ denotes $n$ centred and independent Gaussian random variables with the same covariance matrices:

$$\mathbb{E}(G_i^k G_j^k) = \sigma_{i,j}^k.$$

This is a CLT result (but we stress that it is not asymptotic). And we will obtain an Edgeworth development as well.

We assume that $Z_k$ has finite moments of any order and more precisely,

$$\max_{1 \leq k \leq n} \mathbb{E}(|Z_k|^i) \leq C_i(Z)n^{i/2}.$$  

In particular, for $i = 2$ the inequality (2.2) gives

$$\max_{1 \leq k \leq n} \sup_{i,j} |\sigma_{i,j}^k| \leq \frac{C_2(Z)}{n}.$$  

Since the covariance matrix of $G_k$ is equal to that of $Z_k$, the inequality (2.2) holds for the $G_k$’s as well, so we can resume by writing

$$\sup_{1 \leq k \leq n} \mathbb{E}(|Z_k|^i) \vee \mathbb{E}(|G_k|^i) \leq \frac{C_i(Z)}{n^{i/2}}.$$  

Without loss of generality, (from Hölder) we can assume that $1 \leq C_i(Z) \leq C_{i+1}(Z)$ and more in general

$$1 \leq C_p(Z) \leq C_p^{1/q}(Z), \quad p, q \geq 1.$$  

Remark 2.1. Although it is not explicitly written, we are assuming that we fix $n$ and that the laws of $Z_k$ and $G_k$, as well as $\sigma_k$, are all depending on $n$. In our applications, we take a sequence $Y = \{Y_k\}_k$
of i.i.d. centred r.v’s taking values in \( \mathbb{R}^m \) and we consider \( Z_k = \frac{1}{\sqrt{n}} C_k Y_k \), where \( C_k \) denotes a \( d \times m \) matrix. Therefore, we actually study

\[
S_n = \frac{1}{\sqrt{n}} \sum_{k=1}^{n} C_k Y_k
\]

Notice that

\[
\max_{1 \leq k \leq n} \mathbb{E}(|Z_k|^i) \leq \frac{c_i(Y)}{n^{i/2}} \times \max_{1 \leq k \leq n} \|C_k\|^i,
\]

in which \( c_i(Y) \) denotes a constant depending only on (the law of) the \( Y_k \)'s, so that (2.7) actually holds.

We will specialize the results to this case. But in order to relax the notation and the proofs, it is much more useful to consider a general \( Z_k \) instead of \( \frac{1}{\sqrt{n}} C_k Y_k \).

In order to give the expression of the terms which appear in the Edgeworth development we need to introduce some notation.

We say that \( \alpha \) is a multiindex if \( \alpha \in \{1, \ldots, d\}^k \) for some \( k \geq 1 \), and we set \( |\alpha| = k \) its length. We allow the case \( k = 0 \), giving the void multiindex \( \alpha = \emptyset \).

Let \( \alpha \) be a multiindex and set \( k = |\alpha| \). For \( x \in \mathbb{R}^d \) and \( f : \mathbb{R}^d \to \mathbb{R} \), we denote \( x^\alpha = x_{\alpha_1} \cdots x_{\alpha_k} \) and \( \partial_\alpha f(x) = \partial_{x_{\alpha_1}} \cdots \partial_{x_{\alpha_k}} f(x) \), the case \( k = 0 \) giving \( x^\emptyset = 1 \) and \( \partial_\emptyset f = f \). In the following, we denote with \( C^k(\mathbb{R}^d) \) the set of the functions \( f \) such that \( \partial_\alpha f \) exists and is continuous for any \( \alpha \) with \( |\alpha| \leq k \). The set \( C^k_b(\mathbb{R}^d) \), resp. \( C^k_p(\mathbb{R}^d) \), is the subset of \( C^k(\mathbb{R}^d) \) such that \( \partial_\alpha f \) has polynomial growth, resp. is bounded, for any \( \alpha \) with \( |\alpha| \leq k \). \( C^\infty_p(\mathbb{R}^d) \), resp. \( C^\infty_b(\mathbb{R}^d) \), denotes the intersection of \( C^k(\mathbb{R}^d) \), resp. of \( C^k_b(\mathbb{R}^d) \) and of \( C^k_p(\mathbb{R}^d) \), for every \( k \).

For \( f \in C^k_b(\mathbb{R}^d) \) we denote

\[
\|f\|_{k,\infty} = \|f\|_\infty + \sum_{1 \leq |\alpha| \leq k} \|\partial_\alpha f\|_\infty
\]

and for \( f \in C^k_p(\mathbb{R}^d) \) we define \( L_k(f) \) and \( l_k(f) \) to be some constants such that

\[
\sum_{0 \leq |\alpha| \leq k} |\partial_\alpha f(x)| \leq L_k(f)(1 + |x|)^{l_k(f)}.
\]

Moreover, for a non negative definite matrix \( \sigma \in \mathcal{M}_{d \times d} \) we denote by \( L_\sigma \) the Laplace operator associated to \( \sigma \), i.e.

\[
L_\sigma = \sum_{i,j=1}^{d} \sigma_{ij} \partial_{z_i} \partial_{z_j}.
\]

For \( r \geq 1 \) and \( l \geq 0 \) we set

\[
\Delta_\alpha(r) = \mathbb{E}(Z^\alpha_r) - \mathbb{E}(C^\alpha_r) \quad \text{and} \quad D_r^{(l)} = \sum_{|\alpha| = l} \Delta_\alpha(r) \partial_\alpha.
\]

Notice that \( D_r^{(l)} = 0 \) for \( l = 0, 1, 2 \) and, by (2.4), for \( l \geq 3 \) and \( |\alpha| = l \) then

\[
|\Delta_\alpha(r)| \leq \frac{2C_i(Z)}{n^{l/2}}, \quad r = 1, \ldots, n.
\]

We construct now the coefficients of our development. Let \( N \) be fixed: this is the order of the development that we will obtain. Given \( 1 \leq m \leq k \leq N \) we define

\[
\Lambda_m = \{(l_1, l'_1), \ldots, (l_m, l'_m) : N + 2 \geq l_i \geq 3, \bar{N} := \lfloor N/2 \rfloor \geq l'_i \geq 0, i = 1, \ldots, m\},
\]

\[
\Lambda_{m,k} = \{(l_1, l'_1), \ldots, (l_m, l'_m) \in \Lambda_m : \sum_{i=1}^{m} l_i + 2 \sum_{i=1}^{m} l'_i = k + 2m\}.
\]
Then, for \(1 \leq k \leq N\), we define the differential operator

\[
\Gamma_k = \sum_{m=1}^{k} \sum_{(l_1, l_1', \ldots, l_m, l_m')} \prod_{i=1}^{m} \frac{1}{l_i!} D_{l_i}^{(l_i)} \prod_{j=1}^{m} \left(\frac{-1}{2^{l_i} l_j!}\right) L_{d_j}^{l_j}.
\]  

(2.10)

By using (2.2) and (2.8), one easily gets the following estimates:

\[
|\Gamma_k f(x)| \leq C \times \frac{C_{3k}}{n^{k/2}} \sup_{|\alpha| \leq 3k} |\partial_\alpha f(x)|, \quad f \in C^\infty_{\beta}(\mathbb{R}^d),
\]  

(2.11)

\[
|\Gamma_k f(x)| \leq C \times \frac{C_{3k}}{n^{k/2}} L_{3k}(f)(1 + |x|)^{l_{3k}(f)}, \quad f \in C^\infty_{\beta}(\mathbb{R}^d),
\]  

(2.12)

where \(L_{3k}(f)\) and \(l_{3k}(f)\) are given in (2.3) and \(C, C_{3k}\) are positive constants.

We introduce now the Hermite polynomials. We refer to Nualart [19] for definitions and properties, here we just give the shortest way to introduce them by means of the integration by parts formula. Given a multi-index \(\alpha\), the Hermite polynomial \(H_\alpha\) on \(\mathbb{R}^d\) is defined by

\[
\mathbb{E}(\partial_\alpha f(W)) = \mathbb{E}(f(W) H_\alpha(W)) \quad \forall f \in C^\infty_{\beta}(\mathbb{R}^d)
\]  

(2.13)

where \(W\) is a standard normal random variable in \(\mathbb{R}^d\). Moreover for a differential operator \(\Gamma = \sum_{|\alpha| \leq k} a(\alpha) \partial_\alpha\), with \(a(\alpha) \in \mathbb{R}\), we denote \(H_\Gamma = \sum_{|\alpha| \leq k} a(\alpha) H_\alpha\) so that

\[
\mathbb{E}(\Gamma f(W)) = \mathbb{E}(f(W) H_\Gamma(W)).
\]  

(2.14)

Finally we define

\[
\Phi_N(x) = 1 + \sum_{k=1}^{N} H_{\Gamma_k}(x) \quad \text{with} \quad \Gamma_k \text{ defined in (2.10)}.
\]  

(2.15)

The main result in this section is the following (recall the constants \(L_k(f)\) and \(l_k(f)\), \(f \in C^\infty_{\beta}(\mathbb{R}^d)\), defined in (2.5):

**Theorem 2.2.** Let \(N \in \mathbb{N}\) be given. Then for every \(f \in C^{2N(N+2N)}_{\beta}(\mathbb{R}^d)\)

\[
|\mathbb{E}(f(S_n(Z))) - \mathbb{E}(f(W) \Phi_N(W))| \\
\leq \mathcal{H}_N \frac{C^{2N(N+2N)}_{2(N+3)}(Z)(1 + C_{2l}(f)(Z))^2N+32(N+2)(l(l+1))}{n^{N+1}}
\]  

(2.16)

in which \(N = \lfloor N/2 \rfloor\), \(\hat{N} = N(2N + N + 5)\), \(\mathcal{H}_N\) is a positive constant depending on \(N\) and \(W\) denotes a standard normal random variable in \(\mathbb{R}^d\).

As a consequence, taking \(f(x) = x^\beta\) with \(|\beta| = k\), one gets

\[
|\mathbb{E}(S_n(Z)^\beta) - \mathbb{E}(W^\beta \Phi_N(W))| \leq \mathcal{H}_N \frac{C^{2N(N+2N)}_{2(N+3)}(Z)(1 + C_{2k}(Z))^2N+32(N+2)(k+1)}{n^{N+1}}.
\]  

(2.17)

2.2 Basic decomposition and proof of the main result

Let \(N \in \{0, 1, \ldots\}\). We define

\[
T_{N,x}^0 f(x) = \sum_{l=1}^{N+1} \frac{1}{l!} D_r^{(l)} f(x).
\]  

(2.18)
Since $D_r^{(l)} \equiv 0$ for $l = 0, 1, 2$, the above sum actually begins with $l = 3$ and of course this is the basic fact. Then, with the convention $\sum_{l=3}^2 = 0$, we have

$$T_{N,r}^0 f(x) = \sum_{l=3}^{N+1} \frac{1}{l!} D_r^{(l)} f(x).$$

We also define

$$T_{N,r}^1 f(x) = \frac{1}{(N+2)!} \sum_{|q| = N+3}^N \int_0^1 (1 - \lambda)^{N+2} \mathbb{E}(\partial_\alpha f(x + \lambda Z_r) Z_r^\alpha) d\lambda$$

$$T_{N,r}^1 f(x) = T_{N,r}^1 Z f(x) - T_{N,r}^1 G f(x).$$

For a matrix $P$ we use $P_k,p$ and $P_k,p^0$. By using independence, we have the semigroup and the commutative property:

$$P_{k,p} = P_{k,p}^0 P_{k,r} = P_{k,r}^0 P_{k,p}^0 \quad k \leq r \leq p.$$ (2.24)

Moreover, for $m = 1, \ldots, N$ we denote

$$Q_{N,r_1,\ldots,r_m}^{(m)} = \sum_{\sum_{i=1}^m q_i + \sum_{i=1}^m q'_i > 0} \prod_{i=1}^m \prod_{j=1}^m T_{N,r_i}^{q_i} T_{N,r_j}^{q'_j}$$

$$P_{N,k,n}^{(m)} = \sum_{k \leq r_1 \leq \cdots \leq r_m \leq n} P_{r_m+1, \ldots, r_{m-1}+1, \ldots, r_1}^G \cdots P_{r_1+1, r_2}^G P_{k,p_1}^G Q_{N, r_1, \ldots, r_m}^{(m)}.$$ (2.25)

Notice that in the first sum above the conditions $q_i, q'_i \in \{0, 1\}$ and $q_1 + \cdots + q_m + q'_1 + \cdots + q'_m > 0$ say that at least one of $q_i, q'_i, i = 1, \ldots, m$ is equal to one. We notice that the operators $T_{N,r_i}^0$ and $U_{N,\sigma r_i}^0$ represent “remainders” and they are supposed to give small quantities of order $n^{-\frac{1}{2}(N+1)}$. So the fact that at least one $q_i$ or $q'_i$ is non null means that the product $(\prod_{i=1}^m U_{N,r_i}^{q_i})(\prod_{i=1}^m T_{N,r_i}^{q'_i})$ has at least one term which is a remainder (so is small), and consequently $R_{N,k,n}^{(m)}$ is a remainder also.
Finally we define
\[ Q_{N_1,\ldots, N_{N+1}}^{(N+1)} = \prod_{i=1}^{N+1} (T_{N,r_i}^0 + T_{N,r_i}^1) \quad \text{and} \]
\[ R_{N,k,n}^{(N+1)} = \sum_{k \leq r_1 < \cdots < r_{N+1} \leq n} p_{r_{N+1}, r_{N+1}, r_{N+1}}^Z p_{r_{N+1}, r_{N+1}, r_{N+1}}^G \cdots p_{r_{1}, r_{1}, r_{1}}^G Q_{N_1,\ldots, N_{N+1}}^{(N+1)} \] (2.26)

We are now able to give our first result:

**Proposition 2.3.** Let \( N \geq 1 \) and let \( T_{N,r}^0, h_{N,\sigma_r}^0, R_{N,k,n}^{(m)}, m = 1, \ldots, N+1 \), be given through (2.18), (2.20), (2.25), (2.26). Then for every \( 1 \leq k \leq n+1 \) and \( f \in C_{p}^{N(2N+N+3)}(\mathbb{R}^d) \) one has
\[ P_{k,n+1}^Z f = P_{k,n+1}^G f + \sum_{m=1}^{n} \sum_{k \leq r_1 < \cdots < r_{m} \leq n} P_{k,n+1}^G \left( \prod_{i=1}^{m} T_{N,r_i}^0 \right) \left( \prod_{j=1}^{m} h_{N,\sigma_{r_j}}^0 \right) f + \sum_{m=1}^{n} R_{N,k,n}^{(m)} f. \] (2.27)

**Proof. Step 1 (Lindeberg method)** We use the Lindeberg method in terms of semigroups: for \( 1 \leq k \leq n+1 \)
\[ P_{k,n+1}^Z - P_{k,n+1}^G = \sum_{r=k}^{n} P_{r+1,n+1}^Z (P_{r,r+1}^Z - P_{r,r+1}^G)P_{r,r+1}^G. \]

Then we define
\[ A_{k,p} = 1_{1 \leq k \leq p-1 \leq n} \left( P_{p-1,p}^Z - P_{p-1,p}^G \right) P_{p,p-1}^G \] (2.28)
and the above relation reads
\[ P_{k,n+1}^Z = P_{k,n+1}^G + \sum_{r=k}^{n} P_{r+1,n+1}^Z A_{k,r+1}. \] (2.29)

We will write (2.29) as a discrete time Volterra type equation (this is inspired from the approach to the parametrix method given in [9]: see equation (3.1) there). For a family of operators \( F_{k,p}, k \leq p \) we define \( AF \) by
\[ (AF)_{k,p} = \sum_{r=k}^{p-1} F_{r+1,p} A_{k,r+1} \]
and we write (2.29) in functional form:
\[ P^Z = P^G + AP^Z. \] (2.30)

By iteration,
\[ P^Z = P^G + AP^G + \cdots + A^N P^G + A^{N+1} P^Z. \] (2.31)

By the commutative property in (2.24), straightforward computations give
\[ (A^m P^G)_{k,p} = 1_{1 \leq k \leq m} \sum_{k \leq r_1 < \cdots < r_m \leq p-2} P_{r_{m+1},r_{m+1}}^G \cdots P_{r_{1},r_{1}}^G \left( P_{p-1,p}^Z - P_{p-1,p}^G \right) \times \left( P_{r_{m+1}}^Z - P_{r_{m+1}}^G \right) \left( P_{r_{m+1}}^Z - P_{r_{m+1}}^G \right) \cdots \left( P_{r_{1},r_{1}} - P_{r_{1},r_{1}}^G \right). \] (2.32)

**Step 2 (Taylor formula)** The drawback of (2.31) is that \( A \) depends on \( P^Z \) also, see (2.28). So, we use now the Taylor’s formula in order to eliminate this dependance. We use (2.4) and we consider a
Taylor approximation at the level of an error of order $n^{-N/2}$. We use the following expression for the Taylor’s formula: for $f \in C_{\infty}(\mathbb{R}^d)$,

$$f(x + y) = f(x) + \sum_{p=1}^{N+2} \frac{1}{p!} \sum_{|\alpha|=p} \partial_{\alpha}f(x)y^\alpha + \frac{1}{(N + 2)!} \sum_{|\alpha|=N+3} y^\alpha \int_0^1 (1 - \lambda)^{N+2}\partial_{\alpha}f(x + \lambda y) d\lambda$$

Then we have, with $D^{(i)}_r$ defined in (2.31),

$$(P_{r,1}^Z - P_{r+1}^G) f(x) = \mathbb{E}(f(x + Z_r)) - \mathbb{E}(f(x + G_r))$$

$$= \sum_{i=1}^{N+2} \frac{1}{i!} D^{(i)}_r f(x) + \frac{1}{(N + 2)!} \sum_{|\alpha|=N+3} \int_0^1 (1 - \lambda)^{N+2} \mathbb{E}(\partial_{\alpha}f(x + \lambda Z_r)Z^\alpha) - \mathbb{E}(\partial_{\alpha}f(x + \lambda G_r)G^\alpha) d\lambda$$

$$= T^0_{N,r} f(x) + T^1_{N,r} f(x).$$

By using the independence property, one can apply commutativity and by using (2.32) we have

$$(A^m F)_{k,1} = 1_{1 \leq r < m} \sum_{k \leq r \leq n} P_{m,1}^G \cdots P_{1,1}^G P_{k,1}^G T^0_{N,r} + T^1_{N,r}. \quad (2.33)$$

Notice that the operator in (2.33) acts on $f \in C_{\infty}^{m(N+3)}$. In particular,

$$(A^m P^G)_{k,n} = 1_{1 \leq r \leq m} \sum_{k \leq r \leq n} P_{m,1}^G \cdots P_{1,1}^G P_{k,1}^G (f(x) = \mathbb{E}\left(f\left(x + \sum_{i=k}^{n} G_i - \sum_{j=1}^{m} G_j\right)\right), \quad (2.34)$$

Step 3 (Backward Taylor formula) Since

the chain $P^G_{m,1} \cdots P^G_{1,1} P^G_{k,1} f(x)$ contains all the steps, except for the steps corresponding to $r_i, i = 1, \ldots, m$ (remark that for each $i$, $P^{G}_{r_i,1} P^{G}_{r_i+1}$ is replaced with $T^0_{N,r_i} + T^1_{N,r_i})$. In order to “insert” such steps we use the backward Taylor formula (3.3) up to order $N = [N/2]$ (see next Appendix [3]). So, we take $h^{0}_{N,\sigma_i}$ and $k^{1}_{N,\sigma_i}$ as in (2.20) and (2.21) respectively and we have

$$P^G_{r_i+1,1} P^G_{k,1} f(x) = \mathbb{E}\left(f\left(x + \sum_{i=k}^{r_i} G_i - G_{r_i}\right)\right)$$

$$= \mathbb{E}\left(h^{0}_{N,\sigma_i} f\left(x + \sum_{i=k}^{r_i} G_i\right)\right) + \mathbb{E}\left(h^{1}_{N,\sigma_i} f\left(x + \sum_{i=k}^{r_i} G_i - G_{r_i}\right)\right)$$

$$= P^G_{r_i+1,1} P^G_{k,1} (P^G_{r_i,1} h^{0}_{N,\sigma_i} + h^{1}_{N,\sigma_i}) f(x)$$

$$= P^G_{r_i+1,1} P^G_{k,1} (U^{0}_{N,r_i} + U^{1}_{N,r_i}) f(x),$$

$U^{0}_{N,r_i}$ and $U^{1}_{N,r_i}$ being given in (2.22). We use this formula in (2.34) for every $i = 1, 2, \ldots, m$ and we get

$$(A^m P^G)_{k,n} = \sum_{k \leq r \leq n} P^G_{m,1} \cdots P^G_{1,1} P^G_{k,1} \left(\prod_{i=1}^{m} (U^{0}_{N,r_i} + U^{1}_{N,r_i})\right) \left(\prod_{j=1}^{m} (T^{0}_{N,r_j} + T^{1}_{N,r_j})\right). \quad (2.35)$$
Notice that the above operator acts on $C^m_p(2N + N + 5)(\mathbb{R}^d)$. Our aim now is to isolate the principal term, that is the sum of the terms where only $U_{N,r_i}^0$ and $T_{N,r_i}^0$ appear. So we write

$$(A^m P^G)_{k,n+1} = \sum_{k \leq r_1 \leq \cdots \leq r_m \leq n} P^G_{r_m+1,n+1} \cdots P^G_{r_1+1,r_2} P^G_{k,r_1} \left( \prod_{i=1}^m U_{N,r_i}^0 \right) \left( \prod_{j=1}^m T_{N,r_j}^0 \right)$$

+ \sum_{k \leq r_1 \leq \cdots \leq r_m \leq n} P^G_{r_m+1,n+1} \cdots P^G_{r_1+1,r_2} P^G_{k,r_1} Q_{N,r_1,\ldots,r_m}^{(m)}$$

with $Q_{N,r_1,\ldots,r_m}^{(m)}$ defined in (2.25). The second term is just $R_{N,k,n}^{(m)}$ in (2.25). In order to compute the first one we notice that for every $r' < r < r''$ we have

$$P^G_{r+1,r''} P^G_{r',r} P^G_{r+1,r+1} = P^G_{r',r''}$$

so that

$$P^G_{r_m+1,n+1} \cdots P^G_{r_1+1,r_2} P^G_{k,r_1} \left( \prod_{i=1}^m U_{N,r_i}^0 \right) = P^G_{k,n+1} \left( \prod_{i=1}^m h_{N,\sigma_i}^{0} \right).$$

Then, for $m = 1, \ldots, N$

$$(A^m P^G)_{k,n+1} = \sum_{k \leq r_1 \leq \cdots \leq r_m \leq n} P^G_{k,n+1} \left( \prod_{i=1}^m h_{N,\sigma_i}^{0} \right) \left( \prod_{i=1}^m T_{N,r_i}^0 \right) + R_{N,k,n}^{(m)}.$$ We treat now $A^{N+1} P^Z$. Using (2.33) we get

$$(A^{N+1} P^Z)_{k,n+1} = \sum_{k \leq r_1 \leq \cdots \leq r_{N+1} \leq n} P^Z_{r_{N+1}+1,n+1} \cdots P^G_{r_{1}+1,r_{2}} P^G_{k,r_1} \left( T_{N,r_1}^0 + T_{N,r_1}^1 \right) = R_{N,k,n}^{(N+1)} \cdot$$

which acts on $C^p_p(N+3)$. □

We give now some useful representations of the remainders.

**Lemma 2.4.** Let $m \in \{1, \ldots, N + 1\}$ and $r_1 < \cdots < r_m \leq n$ be fixed. Set $N_m := m(2N + N + 5)$ for $m \leq N$ and $N_m := (N + 1)(N + 3)$ otherwise. Then, the operators $Q_{N,r_1,\ldots,r_m}^{(m)}$ defined in (2.25) for $m = 1, \ldots, N$ and in (2.20) for $m = N + 1$, can be written as

$$Q_{N,r_1,\ldots,r_m}^{(m)}(x) = \sum_{3 \leq |\alpha| \leq N_m} a_{r_1,\ldots,r_m}(\alpha) \theta_{r_1,\ldots,r_m}^{\alpha} \partial_{\alpha} f(x)$$

(2.36)

where $a_{n}(\alpha) \in \mathbb{R}$ are suitable coefficients with the property

$$|a_{r_1,\ldots,r_m}(\alpha)| \leq \frac{CC_2^{N+1}(Z)^m}{n^{N + 3m}}$$

(2.37)

and $\theta_{r_1,\ldots,r_m}^{\alpha} : C^\infty_p(\mathbb{R}^d) \to C^\infty_p(\mathbb{R}^d)$ is an operator which verifies

$$|\theta_{r_1,\ldots,r_m}^{\alpha} \partial_{\alpha} f(x)| \leq 2^{N_m(f)} C_2^{N+1} C_2^{1/2} (Z)(1 + C_2 N_m(f) Z)^m L_m(f)(1 + |x|)^{l_m(f)}$$

(2.38)

$C > 0$ being a suitable constant. Moreover, $\theta_{r_1,\ldots,r_m}^{\alpha}$ can be represented as

$$\theta_{r_1,\ldots,r_m}^{\alpha} f(x) = \int_{(\mathbb{R}^d)^{2m}} f(x + y_1 + \cdots + y_{2m}) \mu_{r_1,\ldots,r_m}^{\alpha}(dy_1, \ldots, dy_{2m})$$

(2.39)

where $\mu_{r_1,\ldots,r_m}^{\alpha}$ is a finite signed measure.
Proof. In a first step we construct the measures $\mu^0_{r_1, \ldots, r_m}$ and the operators $\theta^0_{r_1, \ldots, r_m}$ and in a second step we prove that the corresponding coefficients $a^0_{n_1, \ldots, n_m}(\alpha)$ verify (2.37). We start by representing $T^0_{N,r}$ defined in (2.18). Set

$$\nu^0_{r}(dy) = n^l \Delta_{\alpha}(r) \delta_0(dy), \quad |\alpha| = l \geq 3.$$ 

Notice that if $|\alpha| = l \geq 3$ then $n^l \Delta_{\alpha}(r) \leq 2C_l(Z)$. So, we have

$$T^0_{N,r}f(x) = \sum_{l=3}^{N+2} n^l \sum_{|\alpha|=l} 1 \|R^l \Delta_{\alpha}(r) \delta_0(dy) \quad \text{with}$$

$$\int_{\mathbb{R}^d} (1 + |y|^\gamma) |\nu^0_{r}|(dy) \leq 2C_l(Z), \quad |\alpha| = l \leq N + 2.$$ (2.40)

Hereafter $\gamma$ denotes a non negative power. Concerning $T^1_{N,r}$ in (2.19), for $|\alpha| = N + 3$ set $\lambda^1_{r}(dy) = n^{N+3} \int_0^1 (1 - \lambda)^{N+2} \Delta^\alpha_{\mu Z}(dy) - \mu_{\mu G_i}(dy) d\lambda$, that is

$$\nu^1_{r}(A) = n^{N+3} \int_0^1 (1 - \lambda)^{N+2} \left[ \mathbb{E}(Z^\alpha_{r} 1_{\lambda Z, \in A}) - \mathbb{E}(G^\alpha_{r} 1_{\lambda G, \in A}) \right] d\lambda, \quad |\alpha| = N + 3,$$

for every Borel set $A$. Then we have

$$T^1_{N,r}f(x) = \frac{1}{n^l} \sum_{|\alpha|=N+3} \frac{1}{(N+2)!} \int_{\mathbb{R}^d} \partial_{\alpha} f(x + y) \lambda^1_{r}(dy) \quad \text{with}$$

$$\int_{\mathbb{R}^d} (1 + |y|^\gamma) |\lambda^1_{r}|(dy) \leq \frac{2^{N+3}}{N+3} C_{2(N+3)}^{1/2}(Z)(1 + C_2(Z))^{1/2}, \quad |\alpha| = N + 3.$$ (2.41)

We represent now the operator $U^0_{N,r}f(x) = \mathbb{E}(h^0_{N,r}f(x + G_r))$ with $h^0_{N,r}f$ defined in (2.20). Notice that

$$h^0_{N,r} = \sum_{l=0}^{N} \sum_{|\alpha|=2l} c^0_{r}(\alpha) \partial_{\alpha} \quad \text{with} \quad c^0_{r}(\alpha) = \frac{(-1)^l}{2^l l!} \prod_{k=1}^{l} \sigma^2_{r_{2k-1, 2k}}, \quad |\alpha| = l.$$ 

So, by denoting $\rho^0_{\sigma_r}$ the law of $G_r$, we have

$$U^0_{N,r}f(x) = \mathbb{E}(h^0_{N,r}f(x + G_r)) = \sum_{l=0}^{N} \sum_{|\alpha|=2l} c^0_{r}(\alpha) \int_{\mathbb{R}^d} \partial_{\alpha} f(x + y) \rho^0_{\sigma_r}(dy) \quad \text{with}$$

$$|c^0_{r}(\alpha)| \leq \frac{C_{2}(Z)^l}{2^l l! n^2} \quad \text{and} \quad \int_{\mathbb{R}^d} (1 + |y|^\gamma) |\rho^0_{\sigma_r}|(dy) \leq 2^{\gamma}(1 + C_\gamma(Z)).$$ (2.42)

We now obtain a similar representation for $h^1_{N,r}f(x)$ defined in (2.21). Set

$$\rho^1_{\sigma_r}(dy) = \left( \int_0^1 s^{N} \phi_{\sigma_r} dy \right) ds \quad \text{in which} \quad \phi_{\sigma_r} \quad \text{denotes the density of a centred Gaussian r.v. with covariance matrix} \quad \sigma_r.$$

Then we write

$$h^1_{N,r}f = \sum_{|\alpha|=N+1} b^0_n(\alpha) \int_{\mathbb{R}^d} \partial_{\alpha} f(x + y) \rho^1_{\sigma_r}(dy) \quad \text{with} \quad b^0_n(\alpha) = \frac{(-1)^N}{2^{N+1} n^N} \prod_{k=1}^{N+1} \sigma_{2k-1, 2k}.$$
Since $\bar{N} + 1 \geq (N + 1)/2$, we have

$$U_{N,r}^1 f(x) = h_{N,r}^1 f(x) = \sum_{|\alpha| = 2(N + 1)} b_\alpha^r (\alpha) \int \partial_\alpha f(x + y) \rho_\alpha^r (dy) \quad \text{with}$$

(2.43)

$$|b_\alpha^r (\alpha)| \leq \frac{1}{2^{N+1}N!} C_2 (Z)^{N+1} n^{N+1} \quad \text{and} \quad \int_{\mathbb{R}^d} (1 + |y|)^\gamma |\rho_\alpha^r (dy) \leq \frac{2^\gamma}{\bar{N} + 1} (1 + C_\gamma (Z)).$$

Using (2.40), (2.41), (2.32) and (2.43) we obtain (2.36) with the measure $\mu_\alpha^r_{1,\ldots,r_m}$ from (2.39) constructed in the following way:

$$\int_{\mathbb{R}^d \times 2^n} f(y_1, \ldots, y_m, \bar{y}_1, \ldots, \bar{y}_m) \mu_\alpha^r_{1,\ldots,r_m} (dy_1, \ldots, dy_m, d\bar{y}_1, \ldots, d\bar{y}_m) = \int_{\mathbb{R}^d \times 2^n} f(y_1, \ldots, y_m, \bar{y}_1, \ldots, \bar{y}_m) \eta_1 (dy_1) \cdots \eta_m (dy_m) \cdot \eta_1 (d\bar{y}_1) \cdots \eta_m (d\bar{y}_m)$$

where $\eta_i$ is one of the measures $\nu_{\bar{r}_i}^q$, $q = 0, 1$, and $\bar{\eta}_i$ is one of the measures $\rho_{\bar{r}_i}^q$, $q = 0, 1$.

Let us check that the coefficients $a_{\alpha_{r_1,\ldots,r_m}^r} (\alpha)$ which will appear in (2.36) verify the bounds in (2.37). Take first $m \in \{1, \ldots, N\}$. Then $Q_{N,r_1,\ldots,r_m}^m$ is the sum of $(\prod_{i=1}^m U_{N,r_i}^{q_i} (T_{N,r_i}))$ where $q_i, q_i' \in \{0, 1\}$ and at least one of them is equal to one. And $a_{\alpha_{r_1,\ldots,r_m}^r} (\alpha)$ is the coefficient of measures which appear in the representation of $U_{N,r_i}^{q_i}$ and $T_{N,r_i}^{q_i' r_i}$. Recall that the coefficients of $T_{N,r_i}^{q_i' r_i}$ are all bounded by $CN^{-3/2}$ and the coefficients of $T_{N,r_i}^{r_i}$ are bounded by $CN^{-4/3}$. Moreover the coefficients of $U_{N,r_i}^{r_i}$ are bounded by $CC_2 (Z)$ and the coefficients of $U_{N,r_i}^{q_i}$ are bounded by $CC_2^{N+1} (Z)n^{-(N+1)}$. Therefore, $(\prod_{i=1}^m U_{N,r_i}^{q_i} (T_{N,r_i}))$ is upper bounded by

$$\left( \frac{C}{n^{2(N+3)/3}} \right)^{\sum_{i=1}^m q_i} \times \left( \frac{C}{n^{3/2}} \right)^{\sum_{i=1}^m (1-q_i)} \times \left( \frac{CC_2^{N+1} (Z)}{n^{N+1}} \right)^{\sum_{i=1}^m q_i'} \times (CC_2^{N+1} (Z))^{\sum_{i=1}^m (1-q_i')} \leq \left( \frac{CC_2^{N+1} (Z)}{n^{N+1}} \right)^m \leq \left( \frac{CC_2^{N+1} (Z)}{n^{N+1}} \right)^m \leq \left( \frac{CC_2^{N+1} (Z)}{n^{N+1}} \right)^m.$$

We finally prove (2.38). We have

$$|\partial_{r_1,\ldots,r_m} \partial_\alpha f(x)| \leq \int_{\mathbb{R}^d \times 2^n} |\partial_\alpha f(x + \sum_{i=1}^m y_i + \sum_{j=1}^m \bar{y}_j) | \eta_1 (dy_1) \cdots |\eta_m (dy_m) | \eta_1 (d\bar{y}_1) \cdots |\eta_m (d\bar{y}_m)$$

$$\leq \int_{\mathbb{R}^d \times 2^n} \left( \sum_{i=1}^m \int_{\mathbb{R}^d} (1 + |y|^1)^{\lambda_{N_m} (f)} |\eta_i| (dy_i) \right) \left( \sum_{i=1}^m \int_{\mathbb{R}^d} (1 + |y|^1)^{\lambda_{N_m} (f)} |\eta_i| (dy_i) \right) \leq L_{N_m} (f) (1 + |x|)^{N_m (f)} \left( \sum_{i=1}^m \lambda_{N_m} (f) \right)^m \leq L_{N_m} (f) (1 + |x|)^{N_m (f)} \left( \sum_{i=1}^m \lambda_{N_m} (f) \right)^m.$$
Lemma 2.5. Let the set-up of Proposition 2.3 hold. Then,
\[
\sum_{m=1}^{N} \sum_{1 \leq r_{1} < \ldots < r_{m} \leq n} \left( \prod_{i=1}^{m} T_{N,r_{i}}^{0} \right) \left( \prod_{j=1}^{m} h_{N,\sigma_{r_{j}}}^{0} \right) = \sum_{m=1}^{N} \Gamma_{k} + Q_{N,n}^{0} \tag{2.44}
\]
with \( \Gamma_{k} \) defined in (2.10) and
\[
Q_{N,n}^{0} = \sum_{N+1 \leq |\alpha| \leq N(N+2N)} c_{n}(\alpha) \partial_{\alpha} \quad \text{with} \quad |c_{n}(\alpha)| \leq \frac{(CC_{N+1}(Z)C_{2}(Z))^{N(N+2N)}}{n^{N+1}} \tag{2.45}
\]
Proof. Let \( \Lambda_{m} \) and \( \Lambda_{m,k} \) be the sets in (2.9). Notice that, for fixed \( m \), the \( \Lambda_{m,k} \)'s are disjoint as \( k \) varies. Suppose that \( m \in \{1, \ldots, N\} \). Then \( \Lambda_{m,k} = \emptyset \) if \( k \not\in \{m, \ldots, N(N+2N)\} \) so that \( \Lambda_{m} = \bigcup_{k=m}^{2N(N+2)} \Lambda_{m,k} \) and consequently
\[
\bigcup_{m=1}^{N} \Lambda_{m} = \bigcup_{m=1}^{N} \bigcup_{k=m}^{2N(N+2)} \Lambda_{m,k} = \bigcup_{m=1}^{N} \bigcup_{k=m}^{2N(N+2)} \Lambda_{m,k}.
\]
It follows that
\[
\sum_{m=1}^{N} \sum_{1 \leq r_{1} < \ldots < r_{m} \leq n} \left( \prod_{i=1}^{m} T_{N,r_{i}}^{0} \right) \left( \prod_{j=1}^{m} h_{N,\sigma_{r_{j}}}^{0} \right) \\
= \sum_{m=1}^{N} \sum_{l_{1}, \ldots, l_{m}=1}^{N+2} \sum_{1 \leq r_{1} < \ldots < r_{m} \leq n} \left( \prod_{i=1}^{m} \frac{1}{l_{i}!} D_{r_{i}}^{(l_{i})} \right) \left( \prod_{j=1}^{m} \binom{-1}{2^{l_{j}} l_{j}!} L_{r_{j}}^{l_{j}!} \right) \\
= \sum_{k=1}^{N(N+2N)} \sum_{m=1}^{k} \sum_{(l_{1}, l_{1}', \ldots, m_{m}, m_{m}')} \in \Lambda_{m,k} 1 \leq r_{1} < \ldots < r_{m} \leq n \left( \prod_{i=1}^{m} \frac{1}{l_{i}!} D_{r_{i}}^{(l_{i})} \right) \left( \prod_{j=1}^{m} \binom{-1}{2^{l_{j}} l_{j}!} L_{r_{j}}^{l_{j}!} \right) \\
= \sum_{k=1}^{N} \Gamma_{k} + Q_{N,n}^{0}
\]
with
\[
Q_{N,n}^{0} = \sum_{k=N+1}^{N(N+2N)} \sum_{m=1}^{k} \sum_{(l_{1}, l_{1}', \ldots, m_{m}, m_{m}')} \in \Lambda_{m,k} 1 \leq r_{1} < \ldots < r_{m} \leq n \left( \prod_{i=1}^{m} \frac{1}{l_{i}!} D_{r_{i}}^{(l_{i})} \right) \left( \prod_{j=1}^{m} \binom{-1}{2^{l_{j}} l_{j}!} L_{r_{j}}^{l_{j}!} \right),
\]
which is a differential operator of the form (2.45). Moreover, the coefficients \( c_{n}(\alpha) \) can be bounded as follows:
\[
|c_{n}(\alpha)| \leq n^{m} \times \prod_{i=1}^{m} \left( \frac{1}{l_{i}!} \frac{2C_{N+1}(Z)}{n^{\frac{1}{2}}} \right) \times \prod_{i=1}^{m} \left( \frac{1}{2^{l_{i}} l_{i}!} \frac{C_{2}(Z)}{n^{l_{i}}!} \right) \leq n^{m} \times \frac{(CC_{N+1}(Z)C_{2}(Z))^{m}}{n^{\sum_{i=1}^{m} \frac{1}{2} l_{i}^{2} + l_{i}!}} \leq \frac{(CC_{N+1}(Z)C_{2}(Z))^{m}}{n^{\frac{N+1}{2}}}
\]
and the estimate in (2.45) holds as well. \( \square \)

We are now ready for the
Proof of Theorem 2.2 We denote $P^X_n = P^X_{1,n+1}$, with $X = Z$ or $X = G$, so that

$$\mathbb{E}(f(S_n(Z)) - \mathbb{E}(f(W) \Phi_N(W)) = P^Z_n f(0) - P^G_n \left( \text{Id} + \sum_{k=1}^N \Gamma_k \right) f(0).$$

We have proved that

$$P^Z_n f(x) = P^G_n \left( \text{Id} + \sum_{k=1}^N \Gamma_k \right) f(x) + I_1 f(x) + I_2 f(x) + I_3 f(x) \quad (2.46)$$

with

$$I_1 f(x) = P^G_n Q^0_{N,n} f(x),$$

$$I_2 f(x) = \sum_{1 \leq r_1 < ... < r_{N+1} \leq n} P^G_{r_{N+1}+1,n} P^G_{r_{N+1}+1,r_{N+1}+1} ... P^G_{r_1+1,r_2} P^G_{k,r_1} Q^{(N+1)}_{N,r_1,...,r_{N+1}} f(x) \quad (2.47)$$

$$I_3 f(x) = \sum_{m=1}^N \sum_{1 \leq r_1 < ... < r_m \leq n} P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} \theta^\alpha_{r_1,...,r_m} \partial_\alpha f.$$

so it is sufficient to study the remaining terms $I_1$, $I_2$ and $I_3$ above.

Consider first $m \in \{1, ..., N\}$. We use Lemma 2.4 (recall $N_m$ given therein) and in particular $2.36$:

$$P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} \theta^\alpha_{r_1,...,r_m} f \leq \sum_{3 \leq |a| \leq N_m} a_1 ... a_m(\alpha) P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} \theta^\alpha_{r_1,...,r_m} \partial_\alpha f.$$

Notice that if $|g(x)| \leq L(1 + |x|)^l$ then

$$|P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} g(x)| \leq \mathbb{E}\left(L \left(1 + \left| x + \sum_{k=1}^n G_k 1_{k \notin \{r_1,...,r_m\}} \right) \right)^l \right) \leq L(1 + |x|)^l \mathbb{E}\left(1 + \left| \sum_{k=1}^n G_k 1_{k \notin \{r_1,...,r_m\}} \right| \right)^l \leq L(1 + |x|)^l (1 + \left\| \sum_{k=1}^n G_k 1_{k \notin \{r_1,...,r_m\}} \right\|_l)^l.$$

Since the $G_k 1_{k \notin \{r_1,...,r_m\}}$'s are centred and independent, we can use the Burkholder inequality (see next (3.36)), which gives

$$\left\| \sum_{k=1}^n G_k 1_{k \notin \{r_1,...,r_m\}} \right\|_l \leq \left( \sum_{k=1}^n \left\| G_k 1_{k \notin \{r_1,...,r_m\}} \right\|_l^2 \right)^{1/2} \leq \left( n \sum_{k=1}^n \frac{C^2_l(Z)}{n} \right)^{1/2} \leq C^l_l(Z),$$

and by inserting, we get

$$|P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} g(x)| \leq L(1 + |x|)^l (1 + C^l_l(Z))^l \leq 2^l(1 + C_l(Z))L(1 + |x|)^l.$$

We use now this inequality with $g = \theta^\alpha_{r_1,...,r_m} \partial_\alpha f$: by applying $2.38$ we get

$$|P^G_{r_{m+1}+1,n} P^G_{r_{m+1}+1,r_m} ... P^G_{r_1+1,r_2} P^G_{r_1} Q^{(m)}_{N,r_1,...,r_m} f(x)| \leq K_{N,m}(f) (1 + |x|)^l N_m(f)$$

with

$$K_{N,m}(f) = 2^l N_m(f) \left( 1 + C^l_{N,m}(f) \right) \left( 2^l N_m(f)^2 C^{1/2}_{2l(N+3)}(Z)(1 + C_{2lN_m}(f) Z)^2 \right)^m L_{N_m}(f).$$
Moreover, using (2.37)
\[ |P_{r_m+1,n}^G P_{r_m-1,r_m}^G \cdots P_{r_1+1,r_1}^G P_{r_1-1,r_1}^G Q_{r_1,r_2}^{(m)} f(x)| \]
\[ \leq K_{N,m}(f)(1 + |x|)^{l_{N,m}(f)} \sum_{0 \leq |\alpha| \leq N+1} |a_{r_1 \cdots r_m}(\alpha)| \]
\[ \leq \mathcal{H}_N K_{N,m}(f)(1 + |x|)^{l_{N,m}(f)} (CC_2^{N+1}(Z))^m \times \frac{1}{n^{\frac{N}{2}(N+3m)}}, \]
\[ \mathcal{H}_N \text{ denoting a constant depending on } N \text{ only. Since the set } \{1 \leq r_1 < \ldots < r_m \leq n\} \text{ has less than } n^m \text{ elements, we get} \]
\[ |I_3 f(x)| \leq N \times n^m \times \mathcal{H}_N K_{N,m}(f)(1 + |x|) \times (CC_2^{N+1}(Z))^m \times \frac{1}{n^{\frac{N}{2}(N+3m)}} \]
\[ \leq N \mathcal{H}_N K_{N,m}(f)(1 + |x|)^{l_{N,m}(f)} (CC_2^{N+1}(Z))^m \times \frac{1}{n^{\frac{N}{2}(N+1)}} \]
The estimate for \( I_2(f) \) is analogous. Concerning \( I_1 f \), we use (2.45) in order to obtain
\[ |I_1 f(x)| \leq \sum_{N+1 \leq |\alpha| \leq N(N+2N)} |c_n(\alpha)| |\partial_\alpha f(x)| \]
\[ \leq \sum_{N+1 \leq |\alpha| \leq N(N+2N)} |c_n(\alpha)| L_{N(N+2N)}(1 + |x|)^{l_{N(N+2N)}(f)} \times \left( 1 + \sum_{k=1}^{n} G_k \right)^{l_{N(N+2N)}(f)} \]
\[ \leq \frac{(CC_{N+1}(Z))^{N(N+2N)}}{n^{\frac{N+2N}{2}}} L_{N(N+2N)}(f)(1 + |x|)^{l_{N(N+2N)}(f)} \times \left( 1 + C_{2l(N+2N)}(f)(Z) \right) \]
in which we have again used the Burkholder inequality (3.26). By using \( C_p(Z) \leq C_{pq}(Z) \leq C_{pq}(Z) \), \( q \geq 1 \), we get
\[ \sum_{i=1}^{3} |I_i f(x)| \leq \mathcal{H}_N C_{2l(N+2N)}^{2(N(N+2N))}(Z)(1 + C_{2l(N+2N)}(Z))^{2(N+3)2(N+2)(l_{\hat{N}}(f)+1)} L_{\hat{N}}(f)(1 + |x|)^{l_{\hat{N}}(f)} \times \frac{1}{n^{\frac{N+1}{2}}} \]
with \( \hat{N} = N(2N + N + 5) \), and statement (2.16) follows. Concerning (2.17), it suffices to notice that for \( f(x) = x^\beta \) with \( |\beta| = k \) then \( L_{\hat{N}}(f) = 1 \) and \( l_{\hat{N}}(f) = k \). □

3 General test functions

3.1 Differential calculus based on a splitting method

In this section we use the variational calculus settled in [2, 1, 7, 8] in order to treat general test functions. Let us give the definitions and the notation.

We say that the law of the random variable \( Y \in \mathbb{R}^d \) is locally lower bounded by the Lebesgue measure if there exists \( y_Y \in \mathbb{R}^d \) and \( \varepsilon, r > 0 \) such that for every non negative and measurable function \( f : \mathbb{R}^d \to \mathbb{R}_+ \)
\[ \mathbb{E}(f(Y)) \geq \varepsilon \int f(y - y_Y) 1_{B(0,r)}(y - y_Y) dy. \quad (3.1) \]
We denote by \( \mathcal{L}(r, \varepsilon) \) the class of the random variables which verify (3.1). Given \( r > 0 \) we consider the functions \( a_r, \psi_r : \mathbb{R} \to \mathbb{R}_+ \) defined by
\[ a_r(t) = 1 - \frac{1}{1 - \left( \frac{t}{r} - 1 \right)^2} \quad \psi_r(t) = 1_{\{|t| \leq r\}} + 1_{\{r < |t| \leq 2r\}} e^{a_r(|t|)}. \quad (3.2) \]
If \( Y \in \mathcal{L}(2r, \varepsilon) \) then
\[
\mathbb{E}(f(Y)) \geq \varepsilon \int f(y - y_Y)\psi_r(|y - y_Y|^2)dy.
\]
The advantage of \( \psi_r(|y - y_Y|^2) \) is that it is a smooth function (which replaces the indicator function of the ball) and (it is easy to check) that for each \( l \in \mathbb{N}, p \geq 1 \) there exists a universal constant \( C_{l,p} \geq 1 \) such that
\[
\psi_r(t)|a_r^{(l)}(|t|)|^p \leq \frac{C_{l,p}}{t^{lp}}
\]  
(3.3)
where \( a_r^{(l)} \) denotes the derivative of order \( l \) of \( a_r \). Moreover one can check (see [3]) that if \( Y \in \mathcal{L}(2r, \varepsilon) \) then it admits the following decomposition (the equality is understood as identity of laws):
\[
Y = \chi U + (1 - \chi)V
\]  
(3.4)
where \( \chi, U, V \) are independent random variables with the following laws:
\[
\mathbb{P}(\chi = 1) = \varepsilon m(r) \quad \text{and} \quad \mathbb{P}(\chi = 0) = 1 - \varepsilon m(r),
\]
\[
\mathbb{P}(U \in dy) = \frac{1}{m(r)}\psi_r(|y - y_U|^2)dy
\]
(3.5)
\[
\mathbb{P}(V \in dy) = \frac{1}{1 - \varepsilon m(r)}(\mathbb{P}(Z \in dy) - \varepsilon \psi_r(|y - y_Z|^2)dy)
\]
(3.6)

We are now able to present our calculus. We fix \( r, \varepsilon > 0 \) and we consider a sequence of independent random variables \( Y_k \in \mathcal{L}(2r, \varepsilon), k \in \mathbb{N} \). Then, using the procedure described above we write
\[
Y_k = \chi_k U_k + (1 - \chi_k)V_k,
\]  
(3.7)
the law of \( \chi_k, U_k \) and \( V_k \) being given in [4,5]. We assume that \( \chi_k, U_k, V_k, k \in \mathbb{N} \), are independent. We define \( \mathcal{G} = \sigma(\chi_k, V_k, k \in \mathbb{N}) \). A random variable \( F = f(\omega, U_1, ..., U_n) \) is called a simple functional if \( f \) is \( \mathcal{G} \times \mathcal{B}(\mathbb{R}^{d \times n}) \) measurable and for each \( \omega, f(\omega, \cdot) \in C_b^\infty(\mathbb{R}^{d \times n}) \). We denote \( \mathcal{S} \) the space of the simple functionals. Moreover we define the differential operator \( D : \mathcal{S} \rightarrow l_2 := l_2(\mathbb{R}^d) \) by \( D_{(k,i)}F = \chi_k \partial_{q_k}^i f(\omega, U_1, ..., U_n) \). Then the Malliavin covariance matrix of \( F \in (F^1, ..., F^m) \in \mathcal{S}^m \) is defined as
\[
\sigma_F^{ij} = \langle DF^i, DF^j \rangle_{l_2} = \sum_{k=1}^\infty \sum_{p=1}^d D_{(k,p)}F^i \times D_{(k,p)}F^j, \quad i, j = 1, ..., m.
\]  
(3.8)
If \( \sigma_F \) is invertible we denote \( \gamma_F = \sigma_F^{-1} \).
Moreover, we define the iterated derivatives \( D^m : \mathcal{S} \rightarrow l_2^\otimes m \) by \( D_{(k_1,i_1),..., (k_m,i_m)}^{(m)} = D_{(k_1,i_1)} \cdots D_{(k_m,i_m)} \) and on \( \mathcal{S} \) we consider the norms
\[
|F|^2_q = |F|^2 + \sum_{m=1}^q |D^m F|^2_{l_2^\otimes m} = |F|^2 + \sum_{m=1}^q \sum_{k_1,...,k_m=1}^\infty \sum_{i_1,...,i_m=1}^d |D_{(k_1,i_1)} \cdots D_{(k_m,i_m)} F|^2
\]
and
\[
\|F\|_{q,p} = (\mathbb{E}(|F|_q^p))^{1/p}.
\]  
(3.9)
We introduce now the Ornstein-Uhlenbeck operator $L$. We denote $\theta_{k,i} = \partial_i \ln p_{U_k}(U_k) = 2(U_k - y)^{\perp}1_{r < |U_k - y|^2 < 2}a_{k,i}'(|U_k - y|^2)$, $p_{U_k}$ being the density of $U_k$, and we define

$$LF = - \sum_{k=1}^{\infty} \sum_{i=1}^{d} (D_{(k,i)}D_{(k,i)}F + D_{(k,i)}F \times \theta_{k,i}).$$ \hfill (3.10)

Using elementary integration by parts on $\mathbb{R}^d$ one easily proves the following duality formula: for $F,G \in \mathcal{S}^d$

$$\mathbb{E}(\langle DF, DG \rangle_{l_2}) = \mathbb{E}(FLG) = \mathbb{E}(GLF).$$ \hfill (3.11)

Finally, for $q \geq 2$, we define

$$\|F\|_{q,p} = \|F\|_{q,p} + \|LF\|_{q-2,p}.$$ \hfill (3.12)

We recall now the basic computational rules and the integration by parts formulae. For $\phi \in C^1(\mathbb{R}^d)$ and $F = (F^1, ..., F^d) \in \mathcal{S}^d$ we have

$$D\phi(F) = \sum_{j=1}^{d} \partial_j \phi(F)DF^j,$$ \hfill (3.13)

and for $F,G \in \mathcal{S}$

$$L(FG) = FLG + GLF - 2 \langle DF, DG \rangle.$$ \hfill (3.14)

The formula (3.13) is just the chain rule in the standard differential calculus and (3.14) is obtained using duality. Let $H \in \mathcal{S}$. We use the duality relation and (3.11) we obtain

$$\mathbb{E}(HFLG) = \mathbb{E}(\langle D(HF), DG \rangle_{l_2}) = \mathbb{E}(H \langle DF, DG \rangle_{l_2}) + \mathbb{E}(F \langle DH, DG \rangle_{l_2}).$$

A similar formula holds with $GLF$ instead of $FLG$. We sum them and we obtain

$$\mathbb{E}(H(FLG + GLF)) = 2\mathbb{E}(H \langle DF, DG \rangle_{l_2}) + \mathbb{E}(\langle DH, D(FG) \rangle_{l_2}) = 2\mathbb{E}(H \langle DF, DG \rangle_{l_2}) + \mathbb{E}(HL(FG)).$$

We give now the integration by parts formula (this is a localized version of the standard integration by parts formula from Malliavin calculus).

**Theorem 3.1.** Let $\eta > 0$ be fixed and let $\Psi_{\eta} \in C^\infty(\mathbb{R})$ be such that $1_{\eta/2,\infty} \leq \Psi_{\eta} \leq 1_{\eta,\infty}$ and for every $k \in \mathbb{N}$ one has $\|\Psi_{\eta}^{(k)}\|_{\infty} \leq C\eta^{-k}$. Let $F \in \mathcal{S}^d$ and $G \in \mathcal{S}$. For every $\phi \in C^\infty(\mathbb{R}^d)$, $\eta > 0$ and $i = 1, ..., d$

$$\mathbb{E}(\partial_i \phi(F)G\Psi_{\eta}(\det \sigma_F)) = \mathbb{E}(\phi(F)H_i(F, G\Psi_{\eta}(\det \sigma_F)))$$ \hfill (3.15)

with

$$H_i(F, G\Psi_{\eta}(\det \sigma_F)) = \sum_{j=1}^{d} (G\Psi_{\eta}(\det \sigma_F))^j\gamma_{F,F}^j LF^j + \langle D(G\Psi_{\eta}(\det \sigma_F))^j\gamma_{F,F}^j, DF^j \rangle_{l_2}.$$ \hfill (3.16)

Let $m \in \mathbb{N}, m \geq 2$ and $\alpha = (\alpha_1, ..., \alpha_m) \in \{1, ..., d\}^m$. Then

$$\mathbb{E}(\partial_\alpha \phi(F)G\Psi_{\eta}(\det \sigma_F)) = \mathbb{E}(\phi(F)H_\alpha(F, G\Psi_{\eta}(\det \sigma_F)))$$ \hfill (3.17)

with $H_\alpha(F, G\Psi_{\eta}(\det \sigma_F))$ defined by reccurence

$$H_{(\alpha_1, ..., \alpha_m)}(F, G\Psi_{\eta}(\det \sigma_F)) := H_{\alpha_m}(F, H_{(\alpha_1, ..., \alpha_{m-1})}(F, G\Psi_{\eta}(\det \sigma_F))).$$
Proof. We give here only a sketch of the proof, a detailed one can be found e.g. in [4] and [7]. Using the chain rule \( D\phi(F) = \nabla\phi(F)DF \) so that
\[
\langle D\phi(F), DF \rangle_{L^2} = \nabla\phi(F) \langle DF, DF \rangle_{L^2} = \nabla\phi(F)\sigma_F.
\]
It follows that, on the set \( \det \sigma_F > 0 \), we have \( \nabla\phi(F) = \gamma_F \langle D\phi(F), DF \rangle_{L^2} \). Then, by using (3.15) we get
\[
\mathbb{E}(G\Psi_\eta(\det \sigma_F)\nabla\phi(F)) = \mathbb{E}(G\Psi_\eta(\det \sigma_F)\gamma_F \langle D\phi(F), DF \rangle_{L^2}) = \mathbb{E}(\phi(F)G\Psi_\eta(\det \sigma_F)\gamma_F LF) - \mathbb{E}(\phi(F)\langle (G\Psi_\eta(\det \sigma_F)\gamma_F), DF \rangle_{L^2}).
\]
and (3.15) - (3.16) hold. By iteration one obtains the higher order integration by parts formulae. \( \square \)

We give now useful estimates for the weights which appear in (3.17):

Lemma 3.2. Let \( m, q \in \mathbb{N} \), \( F \in \mathcal{S}^d \) and \( G \in \mathcal{S} \). There exists a universal constant \( C \geq 1 \) (depending on \( d, m, q \) only) such that for every multi index \( \alpha \) with \( |\alpha| = q \) one has
\[
|H_\alpha(F,G\Psi_\eta(\det \sigma_F))|_m \leq C\eta^{-q(m+q+1)}(1 + \|F\|^{2dq(m+q+3)}_{m+q+1}) + |LF|^{2q}_{m+q-1}) |G|_{m+q}. \tag{3.18}
\]
In particular we have
\[
\|H_\alpha(F,G\Psi_\eta(\det \sigma_F))\|_p \leq C\eta^{-(q+1)^2}(1 \vee \|F\|^{2dq(q+3)}_{q+1,4dq(q+3)p}) \|G\|_{q,2p}. \tag{3.19}
\]

Proof. A rather long but straightforward computation (see [7] or [4] Theorem 3.4, more precise details are given in [5]) gives
\[
|H_\alpha(F,G\Psi_\eta(\det \sigma_F))|_m \\leq C(1 \vee (\det \sigma_F)^{-1})^q(m+q+1)(1 + |F|^{2dq(m+q+2)}_{m+q+1}) + |LF|^{2q}_{m+q-1}) |G\Psi_\eta(\det \sigma_F)|_{m+q}.
\]
Notice that
\[
|G\Psi_\eta(\det \sigma_F)|_{m+q} \leq |G|_{m+q} |\Psi_\eta(\det \sigma_F)|_{m+q} \leq C \eta^{m+q} |G|_{m+q} \leq \frac{C}{\eta^{m+q}} |F|^{d}_{m+q}.
\]
Moreover, on the set \( \Psi_\eta(\det \sigma_F) \neq 0 \) we have \( \det \sigma_F \geq \eta/2 \). So
\[
|H_\alpha(F,G\Psi_\eta(\det \sigma_F))|_m \leq C\eta^{-(q+1)(m+q+1)}(1 + |F|^{2dq(m+q+3)}_{m+q+1}) + |LF|^{2q}_{m+q-1}) |G|_{m+q}
\]
so (3.18) is proved. Taking now \( m = 0 \) and using Schwartz inequality we obtain (3.19). \( \square \)

We go now on and we give the regularization lemma. We recall that a super kernel \( \phi : \mathbb{R}^d \rightarrow \mathbb{R} \) is a function which belongs to the Schwartz space \( \mathcal{S} \) (infinitely differentiable functions which decrease in a polynomial way to infinity), \( \int \phi(x)dx = 1 \), and such that for every multi indexes \( \alpha \) and \( \beta \), one has
\[
\int y^\alpha \phi(y)dy = 0, \quad |\alpha| \geq 1, \tag{3.20}
\]
\[
\int |y|^m |\partial_\beta \phi(y)| dy < \infty. \tag{3.21}
\]
As usual, for \( |\alpha| = m \) then \( y^\alpha = \prod_{i=1}^m y_{a_i} \). Since super kernels play a crucial role in our approach we give here the construction of such an object (we follow [7] Section 3, Remark 1). We do it in dimension

\[\text{...} \]
\(d = 1\) and then we take tensor products. So, if \(d = 1\) we take \(\psi \in S\) which is symmetric and equal to one in a neighborhood of zero and we define \(\phi = \mathcal{F}^{-1}\psi\), the inverse of the Fourier transform of \(\psi\). Since \(\mathcal{F}^{-1}\) sends \(S\) into \(S\) the property (3.21) is verified. And we also have \(0 = \psi^{(m)}(0) = i^{-m} \int x^m \phi(x)dx\) so (3.20) holds as well. We finally normalize in order to obtain \(\int \phi = 1\).

We fix a super kernel \(\phi\). For \(\delta \in (0, 1)\) and for a function \(f\) we define

\[
\phi_\delta(y) = \frac{1}{\delta^d} \phi\left(\frac{y}{\delta}\right) \quad \text{and} \quad f_\delta = f \ast \phi_\delta,
\]

the symbol \(\ast\) denoting convolution. For \(f \in C^k_p(\mathbb{R}^d)\), we recall the constants \(L_k(f)\) and \(l_k(f)\) in (2.5).

**Lemma 3.3.** Let \(F \in S^d\) and \(q, m \in \mathbb{N}\). There exists a constant \(C \geq 1\), depending on \(d, m\) and \(q\) only, such that for every \(f \in C^q_{C^m}(\mathbb{R}^d)\), every multi index \(\gamma\) with \(|\gamma| = m\) and every \(\eta, \delta > 0\)

\[
|\mathbb{E}(\Psi_\eta(\det \sigma_F)) \partial_\gamma f(x + F) - \mathbb{E}(\Psi_\eta(\det \sigma_F)) \partial_\gamma f_\delta(x + F)|
\]

\[
\leq C l_0(f + q) L_0(f) \|F\|_{2q(f)}^{q+q} C_{q+m}(f) \frac{\delta^q}{\eta(q+m+1)^2} (1 + |x|)^{l_0(f)}
\]  \( (3.22)\)

with

\[
c_p = \int |\phi(z)| (1 + |z|)^p dz \quad \text{and} \quad C_p(F) = 1 \vee \|F\|^{2dp(p+3)}_{p+1,4p(p+3)}.
\]  \( (3.23)\)

As a consequence, we have

\[
|\mathbb{E}(\partial_\gamma f(x + F)) - \mathbb{E}(\partial_\gamma f_\delta(x + F))|
\]

\[
\leq C \|F\|_{2q(f)}^{l_0(f)} \left(c_m(f)L_m(f)\|\partial_\gamma \sigma_F \leq \eta\| + \frac{c_0(f) + q\delta^q}{\eta(q+m+1)^2} \|L_0(f)C_{q+m}(f)\right) (1 + |x|)^{l_0(f)}.
\]  \( (3.24)\)

**Proof A.** Using Taylor expansion of order \(q\)

\[
\partial_\gamma f(x) - \partial_\gamma f_\delta(x) = \int \partial_\gamma f(x) - \partial_\gamma f(y) \phi_\delta(x - y) dy
\]

\[
= \int L_{\gamma,q}(x,y) \phi_\delta(x - y) dy + \int R_{\gamma,q}(x,y) \phi_\delta(x - y) dy
\]

with

\[
L_{\gamma,q}(x,y) = \sum_{i=1}^{q-1} \frac{1}{q!} \sum_{|\alpha| = i} \partial_\alpha \partial_\gamma f(x - y)^\alpha,
\]

\[
R_{\gamma,q}(x,y) = \frac{1}{q!} \sum_{|\alpha| = q} \int_0^1 \partial_\alpha \partial_\gamma f(x + \lambda(y - x))(x - y)^\alpha(1 - \lambda)^q d\lambda.
\]

Using (3.20) we obtain \(\int L(x,y) \phi_\delta(x - y) dy = 0\) and by a change of variable we get

\[
\int R_{\gamma,q}(x,y) \phi_\delta(x - y) dy = \frac{1}{q!} \sum_{|\alpha| = q} \int_0^1 dz \phi_\delta(z) \partial_\alpha \partial_\gamma f(x + \lambda z)^\alpha(1 - \lambda)^q d\lambda.
\]

So, we have

\[
\mathbb{E}(\Psi_\eta(\det \sigma_F) \partial_\gamma f(x + F)) - \mathbb{E}(\Psi_\eta(\det \sigma_F) \partial_\gamma f_\delta(x + F))
\]

\[
= \mathbb{E}(\int \Psi_\eta(\det \sigma_F) R_{\gamma,q}(x + F, y) \phi_\delta(x + F - y) dy)
\]

\[
= \frac{1}{q!} \sum_{|\alpha| = q} \int_0^1 dz \phi_\delta(z) \mathbb{E}(\Psi_\eta(\det \sigma_F) \partial_\alpha \partial_\gamma f(x + F + \lambda z)) z^\alpha(1 - \lambda)^q d\lambda.
\]
Using integration by parts formula (3.17) (with $G = 1$)
\[
|\mathbb{E}(\Psi_{\eta}(\det \sigma_F) \partial_{\alpha} \partial_{\gamma} f(x + F + \lambda z))|
\]
\[
= |\mathbb{E}(f(F + \lambda z) H_{(\gamma, \alpha)}(F, \Psi_{\eta}(\det \sigma_F))|
\]
\[
\leq L_0(f) \mathbb{E}((1 + |x| + |z| + |F|) \eta_0(f) |H_{(\gamma, \alpha)}(F, \Psi_{\eta}(\det \sigma_F))|
\)
\[
\leq C(1 + |x|) \eta_0(f)(1 + |z|) \eta_0(f) L_0(f) \|F\|_{2 \alpha_0(f)} \mathbb{E}(|H_{(\gamma, \alpha)}(F, \Psi_{\eta}(\det \sigma_F))|^2)^{1/2}.
\]
and the upper bound from (3.19) (with $p = 2$) we get
\[
(\mathbb{E}(|H_{(\alpha, \gamma)}(F, \Psi_{\eta}(\det \sigma_F))|^2)^{1/2} \leq \frac{C}{\eta^{(q+m+1)^2}} (1 \vee \|F\|^2 \|F\|^2_{q+m+1, 4d(q+m)(q+m+3)})
\]
And since $\int dz |\phi_\delta(z) z^\alpha| (1 + |z|) \eta_0(f) \leq \delta^q \int |\phi(z) z^\alpha| (1 + |z|) \eta_0(f) dz$ we conclude that
\[
|\mathbb{E}(\Psi_{\eta}(\det \sigma_F)) \partial_{\gamma} f(F)) - \mathbb{E}(\Psi_{\eta}(\det \sigma_F)) \partial_{\gamma} f_\delta(F))|
\]
\[
\leq C(1 + |x|) \eta_0(f) c_\eta(f_0) L_0(f) \|F\|^2 \|2 \eta_0(f) C_{q+m}(F) \frac{C \delta^q}{\eta^{(q+m+1)^2}}, \quad c_\eta(f) = \int |\phi(z)| (1 + |z|) \eta_0(f) + q dz
\]
and (3.22) holds. Concerning (3.24), we write
\[
|\mathbb{E}((1 - \Psi_{\eta}(\det \sigma_F)) \partial_{\gamma} f(x + F)) - \mathbb{E}((1 - \Psi_{\eta}(\det \sigma_F)) \partial_{\gamma} f_\delta(x + F))|
\]
\[
\leq 2 L_0(\partial_{\gamma} f_\delta) \vee L_0(\partial_{\gamma} f) \mathbb{E}((1 - \Psi_{\eta}(\det \sigma_F))(1 + |x| + |F|) \eta_0(\partial_{\gamma} f) \vee \eta_0(\partial_{\gamma} f))
\]
\[
\leq 2 L_0(\partial_{\gamma} f_\delta) \vee L_0(\partial_{\gamma} f) (1 + |x|) \eta_0(\partial_{\gamma} f) \vee \eta_0(\partial_{\gamma} f) \|F\| \|2 \eta_0(f_\delta) \| \|2 \eta_0(f) \|^{1/2} (\det \sigma_F \leq \eta).
\]
So the proof of (3.24) will be completed as soon as we check that $l_0(\partial_{\gamma} f_\delta) \leq l_m(f)$ and $L_0(\partial_{\gamma} f_\delta) \leq L_m(f) (1 + |y|) \eta_0(f) |\phi(y)| dy:
\[
|\partial_{\gamma} f_\delta(x)| = \left| \int \partial_{\gamma} f(x - y) \phi_\delta(y) dy \right| \leq L_m(f) (1 + |x - y|) \eta_0(f) |\phi_\delta(y)| dy
\]
\[
\leq L_m(f) (1 + |x|) \eta_0(f) \int (1 + |y|) \eta_0(f) |\phi(y)| dy.
\]
\[
\square
\]

### 3.2 CLT and Edgeworth’s development

In this section we take $F = S_n(Z) = \sum_{k=1}^n Z_k$ defined in (2.1). It is convenient for us to write $\sigma_k = C_k C_k^*$ with $C_k \in M_{d \times d}$ symmetric and $Z_k = C_k Y_k$. So $S_n(Z) = \sum_{k=1}^n C_k Y_k$. We assume that $Y_k \in \mathcal{L}(2r, \varepsilon)$ so we have the decomposition (3.7). Consequently
\[
F = S_n(Z) = \sum_{k=1}^n C_k Y_k = \sum_{k=1}^n C_k (\chi_k U_k + (1 - \chi_k)V_k).
\]
We will use Lemma 3.3 so we estimate the quantities which appear in the right hand side of (3.22).

**Lemma 3.4.** For every $k \in \mathbb{N}$ and $p \geq 1$ there exists a constant $C$ depending on $k, p$ only, such that
\[
\sup_n \|S_n(Z)\|_{k,p} \leq C \times \frac{C_p(Z)}{p^k}.
\](3.25)
Proof. We will use the following easy consequence of Burkholder’s inequality for discrete martingales: if $M_n = \sum_{k=1}^{n} \Delta_k$ with $\Delta_k, k = 1, \ldots, n$ independent centred random variables, then
\[
\|M_n\|_p \leq C \mathbb{E}\left( \left( \sum_{k=1}^{n} |\Delta_k|^2 \right)^{p/2} \right)^{1/p} = C \left\| \sum_{k=1}^{n} |\Delta_k|^2 \right\|_{p/2}^{1/2} \leq C \left( \sum_{k=1}^{n} \|\Delta_k\|_p^2 \right)^{1/2}. \tag{3.26}
\]
Using this inequality and (2.4) we obtain $\|S_n(Z)\|_p \leq C \times C_p(Z)$. We look now to the Sobolev norms. It is easy to see that, $S_n(Z)^i$ denoting the $i$th component of $S_n(Z)$,
\[D_{(k,j)}S_n(Z)^i = \chi_k C_k^{i,j} \quad \text{and} \quad D^{(l)}S_n(Z) = 0 \text{ for } l \geq 2.\]
Since $\sum_{k=1}^{n} |\sigma_k| \leq C(Z)$ it follows that
\[\|S_n(Z)\|_{k,p} \leq 2C_p(Z) \quad \forall k \in \mathbb{N}, p \geq 2.\]
Moreover
\[LS_n(Z) = -\sum_{k=1}^{n} LZ_k = -\sum_{k=1}^{n} \chi_k C_k A_r(U_k), \quad A_r(U_k) = 1_{r<|U_k-y|2<2r} \times 2a_r(|U_k-y|2)(U_k-yY).\]
We prove that
\[\|LS_n(Z)\|_{k,p} \leq \frac{C}{r^k} \times C_p(Z), \tag{3.27}\]
$C$ depending on $k, p$ but being independent of $n$.

Let $k = 0$. The duality relation gives $\mathbb{E}(LZ_k) = \mathbb{E}(\langle D1, DZ_k \rangle_{l_2}) = 0$. Since the $LZ_k$’s are independent, we can apply (3.26) first and (2.4), so that
\[
\|LS_n(Z)\|_p \leq C \left( \sum_{k=1}^{n} \|C_k A_r(U_k)\|_p^2 \right)^{1/2} \leq \left( \sum_{k=1}^{n} \frac{C_2(Z)}{n} \|A_r(U_k)\|_p^2 \right)^{1/2}.
\]
By (3.3) $\mathbb{E}(|A_r(U_k)|^p) \leq Cr^{-p}$ so $\|LS_n(Z)\|_p \leq Cr^{-1} \times C_2(Z)$.
We take now $k = 1$. We have
\[D_{(q,j)}LS_n(Z)^i = D_{(q,j)}(\chi_k C_q A_r(U_q)) = \chi_k C_q D_{(q,j)} A_r(U_q),\]
so that, using again (2.4),
\[|DLS_n(Z)|_{l_2}^2 = \sum_{q=1}^{n} \sum_{j=1}^{d} |\chi_k C_q D_{(q,j)} A_r(U_q)|^2 \leq C \times \frac{C_2(Z)}{n} \sum_{q=1}^{n} \sum_{j=1}^{d} \|D_{(q,j)} A_r(U_q)\|_p^2.\]
We notice that $D_{(q,j)} A_r(U_q)$ is not null for $r < |U_q-y|2 < 2r$ and contains the derivatives of $a_r$ up to order 2, possibly multiplied by polynomials in the components of $U_q-yY$ of order up to 2. Since $|U_q-yY|^2 \leq 2r$, by using (3.3) one obtains $\mathbb{E}(|DLF|^p) \leq Cr^{-2p} \times C_2^{1/2}(Z)$, so (3.27) holds for $k = 1$ also. And for higher order derivatives the proof is similar. □

We give now estimates of the Malliavin covariance matrix. We have
\[\sigma S_n(Z) = \sum_{k=1}^{n} \chi_k \sigma_k.\]
We denote
\[ \overline{\sigma}_n = \sum_{i=1}^{n} \sigma_i, \quad \Delta_n = \inf_{|\xi|=1} \langle \overline{\sigma}_n \xi, \xi \rangle, \quad \bar{\lambda}_n = \sup_{|\xi|=1} \langle \overline{\sigma}_n \xi, \xi \rangle. \] (3.28)

For reasons which will be clear later on we do not consider here the normalization condition \( \overline{\sigma}_n = \text{Id.} \) We have the following result.

**Lemma 3.5.** Let \( \eta = \left(\frac{\lambda_m(r)}{2(1+2\lambda_n)}\right)^d \). Then
\[
\mathbb{P}(\det \sigma_{S_n(Z)} \leq \eta) \leq \frac{e^{3\tau_d}}{9} \left(\frac{2(1+2\lambda_n)}{\Delta_n m(r)}\right)^d \exp \left( -\frac{\lambda^2 m^2(r)}{16\lambda_n} \times n \right).
\] (3.29)

\( \tau_d \) denoting a positive constant depending on the dimension \( d \) only and \( \bar{\lambda}_n \) and \( \Delta_n \) being given in (3.28).

**Proof.** Since \( \sigma_k = C_k C_k^* \) we have
\[
\langle \sigma_{S_n(Z)} \xi, \xi \rangle = \sum_{k=1}^{n} \chi_k \langle \sigma_k \xi, \xi \rangle = \sum_{k=1}^{n} \chi_k |C_k \xi|^2.
\]

Take \( \xi_1, \ldots, \xi_N \in S_{d-1} = \{ \xi \in \mathbb{R}^d : |\xi| = 1 \} \) such that the balls of centers \( \xi_i \) and radius \( \eta^{1/d} \) cover \( S_{d-1} \). One needs \( N \leq \tilde{c}_d \eta^{-1} \) points, where \( \tilde{c}_d \) is a constant depending on the dimension. It is easy to check that \( \xi \mapsto \langle \sigma_{S_n(Z)} \xi, \xi \rangle \) is Lipschitz continuous with Lipschitz constant \( 2\lambda_n \) so that \( \inf_{|\xi|=1} \langle \sigma_{S_n(Z)} \xi, \xi \rangle \geq \inf_{i=1, \ldots, N} \langle \sigma_k \xi, \xi \rangle - 2\lambda_n \eta^{1/d} \). Consequently,
\[
\mathbb{P}(\det \sigma_{S_n(Z)} \leq \eta) \leq \mathbb{P}( \inf_{|\xi|=1} \langle \sigma_{S_n(Z)} \xi, \xi \rangle \leq \eta^{1/d} ) \leq \sum_{i=1}^{N} \mathbb{P}( \langle \sigma_{S_n(Z)} \xi_i, \xi_i \rangle \leq \eta^{1/d} + 2\lambda_n \eta^{1/d} )
\leq \frac{\tilde{c}_d}{\eta} \max_{i=1, \ldots, N} \mathbb{P}( \langle \sigma_{S_n(Z)} \xi_i, \xi_i \rangle \leq \eta^{1/d}(1 + 2\lambda_n) ).
\]

So, it remains to prove that for every \( \xi \in S_{d-1} \) and for the choice \( \eta = \left(\frac{\lambda_m(r)}{2(1+2\lambda_n)}\right)^d \),
\[
\mathbb{P}(\langle \sigma_{S_n(Z)} \xi, \xi \rangle \leq (1 + 2\lambda_n) \eta^{1/d} ) \leq \frac{2e^{3\tau_d}}{9} \exp \left( -\frac{\lambda^2 m^2(r)}{16\lambda_n} \times n \right).
\]

We recall that \( \mathbb{E}(\chi_k) = m(r) \) and we write
\[
\mathbb{P}(\langle \sigma_{S_n(Z)} \xi, \xi \rangle \leq (1 + 2\lambda_n) \eta^{1/d} ) = \mathbb{P}\left( \sum_{k=1}^{n} (\chi_k - m(r)) |C_k \xi|^2 \leq (1 + 2\lambda_n) \eta^{1/d} - m(r) \sum_{k=1}^{n} |C_k \xi|^2 \right)
\leq \mathbb{P}\left( -\sum_{k=1}^{n} (\chi_k - m(r)) |C_k \xi|^2 \geq \Delta_n m(r) - (1 + 2\lambda_n) \eta^{1/d} \right)
\]
the last equality being true because
\[
\sum_{k=1}^{n} |C_k \xi|^2 = \sum_{k=1}^{n} \langle \sigma_k \xi, \xi \rangle \geq \Delta_n |\xi|^2 = \Delta_n.
\]

So, we take \( \eta = \left(\frac{\lambda_m(r)}{2(1+2\lambda_n)}\right)^d \) and we get
\[
\mathbb{P}(\langle \sigma_{S_n(Z)} \xi, \xi \rangle \leq (1 + 2\lambda_n) \eta^{1/d} ) \leq \mathbb{P}\left( -\sum_{k=1}^{n} (\chi_k - m(r)) |C_k \xi|^2 \geq \frac{\lambda_m(r)}{2} \right)
\]
We now use the following Hoeffding’s inequality (in the slightly more general form given in Corollary 1.4): if the differences $X_k$ of a martingale $M_n$ are such that $\mathbb{P}(|X_k| \leq b_k) = 1$ then $\mathbb{P}(M_n \geq x) \leq (2e^3/9) \exp(-|x|^2 \times n / (2(b_1^2 + \cdots + b_n^2)))$. Here, we choose $X_k = -(\chi_k - m(r)) |C_k \xi|^2$. These are independent random variables and $|X_k| \leq 2 |C_k \xi|^2$. Then

$$
P\left(- \sum_{k=1}^{n} (\chi_k - m(r)) |C_k \xi|^2 \geq \frac{\lambda_m(r)}{2} \right) \leq \frac{2e^3}{9} \exp\left( - \frac{\lambda_m^2(r)}{4} \times \frac{n}{\sum_{k=1}^{n} |C_k \xi|^2} \right) \leq \frac{2e^3}{9} \exp\left( - \frac{\lambda_m^2(r)}{16 \lambda_n} \times n \right).
$$

\[\square\]

We are now able to give the regularization lemma in our specific framework.

**Lemma 3.6.** Let $q, m \in \mathbb{N}$. There exists some constant $C \geq 1$, depending just on $q, m$, such that for every $\delta > 0$, every multi index $\gamma$ with $|\gamma| = m$ and every $f \in C^m_p(\mathbb{R}^d)$ one has

$$
|\mathbb{E}(\partial_{\gamma} f(x + S_n(Z))) - \mathbb{E}(\partial_{\gamma} f_\delta(x + S_n(Z)))| 
\leq C C_{2l_0(f)}^{1/2}(Z) Q_{q,m}(Z) \left( L_m(f) \exp\left( - \frac{\lambda_m^2(r)}{32 \lambda_n} \times n \right) + \delta^q L_0(f) \right) (1 + |x|)^{l_m(f)}
$$

(3.30)

with

$$
Q_{q,m}(Z) = \frac{C^{2d(q+m)(q+m+3)}_{4d(q+m)(q+m+3)}(Z)}{c_p^{2d(q+m)^2}} \left( 1 + \frac{2 \lambda_n}{\lambda_m(r)} \right) d(q+m+1)^2 \frac{\lambda_m(r)}{c_m(f)\vee(l_0(f)+q)}.
$$

(3.31)

c_p being given in (3.23).

**Proof.** We will use Lemma 3.3. Notice first that, by (3.23), the constant $C_{q+m}(S_n(Z))$ defined in (3.23) is upper bounded by

$$
C C_{2l_0(f)}^{1/2}(Z) r^{-(q+m+1)},
$$

$C$ depending on $d$ and $q + m$. And by using the Burkholder inequality (3.26), one has $||S_n(Z)||_{2l_0(f)} \leq C_{2l_0(f)}^{1/2}(Z)$. So (3.24) gives

$$
|\mathbb{E}(\partial_{\gamma} f(x + S_n(Z))) - \mathbb{E}(\partial_{\gamma} f_\delta(x + S_n(Z)))| 
\leq \frac{CC_{2l_0(f)}^{1/2}(Z)}{c_p^{2d(q+m)^2}} C_{4d(q+m)(q+m+3)}^{2d(q+m)(q+m+3)}(Z) d(q+m+1)^2 \frac{\lambda_m(r)}{c_m(f)\vee(l_0(f)+q)} \left( L_m(f) \exp\left( - \frac{\lambda_m^2(r)}{32 \lambda_n} \times n \right) + \delta^q L_0(f) \right) \times (1 + |x|)^{l_m(f)},
$$

c_p(f) being given in (3.23). We take now $\eta = \frac{\lambda_m(r)}{2(1 + \lambda_n)}$ and we use (3.29) in order to obtain

$$
|\mathbb{E}(\partial_{\gamma} f(x + S_n(Z))) - \mathbb{E}(\partial_{\gamma} f_\delta(x + S_n(Z)))| 
\leq \frac{CC_{2l_0(f)}^{1/2}(Z)}{c_p^{2d(q+m)^2}} C_{4d(q+m)(q+m+3)}^{2d(q+m)(q+m+3)}(Z) d(q+m+1)^2 \frac{\lambda_m(r)}{c_m(f)\vee(l_0(f)+q)} \times (1 + \frac{2 \lambda_n}{\lambda_m(r)}) \left( L_m(f) \exp\left( - \frac{\lambda_m^2(r)}{32 \lambda_n} \times n \right) + \delta^q L_0(f) \right) (1 + |x|)^{l_m(f)}
$$

\[\square\]

We are now able to characterize the regularity of the semigroup $P_n^Z$:
We estimate first

\[ \left| \mathbb{E}(\partial_\gamma f(x + S_n(Z))) \right| \leq \left( L_m(f) C_{2m}^2 \right) \frac{C(1 + C_{2m}(f)(Z))(1 + 2\lambda_n^{d/2})}{\lambda_n^{m(r)} d/2} \exp\left( -\frac{\lambda_n^{m(r)} d/2}{32} \times n \right) \]

Proof. We take \( \eta = \frac{\lambda_n^{m(r)}}{2(1 + \lambda_n^{d/2})} \) and the truncation function \( \Psi \) and we write

\[ \mathbb{E}(\partial_\gamma f(x + S_n(Z))) = I + J \]

with

\[ I = \mathbb{E}(\partial_\gamma f(x + S_n(Z))(1 - \Psi_n(\det \sigma S_n))), \quad J = \mathbb{E}(\partial_\gamma f(x + S_n(Z))\Psi_n(\det \sigma S_n)). \]

We estimate first

\[ |I| \leq L_m(f) \mathbb{E}\left((1 + |x| + |S_n(Z)|)^{2m(f)}(1 - \Psi_n(\det \sigma S_n))\right) \]

\[ \leq L_m(f) \mathbb{E}\left((1 + |x| + |S_n(Z)|)^{2m(f)}(1 - \Psi_n(\det \sigma S_n))\right)^{1/2} \mathbb{E}(\det \sigma S_n \leq \eta) \]

\[ \leq C L_m(f) \mathbb{E}\left((1 + |x|)^{2m(f)}(1 + C_{2m}(f)(Z))(1 + \lambda_n^{d/2})\right)^{d/2} \exp\left( -\frac{\lambda_n^{m(r)} d/2}{32} \times n \right). \]

In order to estimate \( J \) we use integration by parts and we obtain

\[ J = \mathbb{E}(f(x + S_n(Z))H_\gamma(S_n(Z), \Psi_n(\det \sigma S_n))) \]

\[ \leq L_0(f) \mathbb{E}\left((1 + |x|)^{2m(f)}(1 + C_{2m}(f)(Z))(1 + \lambda_n^{d/2})\left( H_\gamma(S_n(Z), \Psi_n(\det \sigma S_n)) \right) \right)^{1/2}. \]

Then using (3.19) and (3.25)

\[ \left\| H_\gamma(S_n(Z), \Psi_n(\det \sigma S_n)) \right\|_2 \leq C \eta^{-d(m+1)}(1 + \|S_n(Z)\|^{2m(m+1)\lambda_n}) \]

\[ \leq C \eta^{-d(m+1)}(1 + \|S_n(Z)\|^{2m(m+1)\lambda_n}) \]

\[ \leq C \eta^{-d(m+1)}(1 + \|S_n(Z)\|^{2m(m+1)\lambda_n}). \]

We are now able to give the main result.

**Theorem 3.8.** We look to \( S_n(Z) = \sum_{k=1}^n Z_k = \sum_{k=1}^n C_k Y_k \) and we assume that \( Y_k \in \mathcal{L}(2r, \varepsilon) \) for some \( \varepsilon > 0, r > 0 \). We also assume that (3.7) and (3.9) hold (for every \( p \in \mathbb{N} \)). Let \( N, q \in \mathbb{N} \) be fixed. We assume that \( n \) is sufficiently large in order to have

\[ \eta^{1/2} n^{(N+1)} e^{-\frac{m^2(r)}{128} \times n} \leq 1 \quad \text{and} \quad n \geq 4(N + 1)C_2(Z). \]

There exists \( C \geq 1 \), depending on \( N \) and \( q \) only, such that for every multi index \( \gamma \) with \( |\gamma| = q \) and every \( f \in C_p^p(\mathbb{R}^d) \)

\[ \left| \mathbb{E}(\partial_\gamma f(S_n(Z))) - \mathbb{E}(\partial_\gamma f(W)\Phi_N(W)) \right| \leq C \times C_n(Z) \frac{1}{n^{1/4(N+1)}} L_0(f) + L_q(f) e^{-\frac{m^2(r)}{128} \times n}. \]
where
\[ C_\ast(Z) = (C_2^{N+1}(Z))^{N+1}z^{(N+1)(l_0(f)+1)+2} (1 + C_{2l_0(f)}(Z))^{2N+3} \]
\[ \times \frac{C_{p_1}(Z)}{r^{p_1+1}m(r)^{d(p_1+1)}} l_0(f) + q + (N+1)(N+3) \]  
(3.34)

with \( p_1 = 2q + (N+1)(N+3), \) \( p_2 = 8dp_1(p_1 + 3), \) \( p_3 = 2dp_1(p_1 + 3) + \frac{N+1}{2} \) (3.35)
\( c_p \) being given in \( (3.25) \).

**Proof. Step 1.** We assume first that \( f \in C_p^{q+(N+1)(N+3)}(\mathbb{R}^d) \) and we prove that
\[
\left| \mathbb{E}(\partial_x f(S_\alpha(Z))) - \mathbb{E}(\partial_x f(W)\Phi_N(W)) \right| 
\leq \frac{\tilde{C}_1}{n^\frac{1}{2}(N+1)} (L_{q+(N+1)(N+3)}(f) 2^{q+(N+1)(N+3)} e^{-\frac{n^2(x)}{64}} + L_0(f) 2^{l_0(f)}),
\]
(3.36)
where
\[
\tilde{C}_1 = (C_2^{N+1}(Z))^{N+1}C_{2(N+3)}^{(N+1)/2}(Z)B_{q+(N+1)(N+3)} \quad \text{with} \quad
B_p = (2^{p(f)+1}(1 + C_{2p(f)}(Z))^{2N+3})^2 \frac{C}{r^{p+1}m(r)^{d(p+1)}} \times (1 + C_{2p(f)}(Z)) \times C_{8dp(p+3)}^{dp(p+3)}(Z).
\]

Notice that (3.36) is analogous to (3.38) but here \( L_q(f) \) and \( l_q(f) \) are replaced by \( L_{q+(N+1)(N+3)}(f) \) and \( l_{q+(N+1)(N+3)}(f) \).

We recall that in (2.46) and (2.47) we have proved that
\[
P_n^Z \partial_x f(x) = P_n^G(Id + \sum_{k=1}^{N} \Gamma_k) \partial_x f(x) + I_1(\partial_x f(x)) + I_2(\partial_x f(x)) + I_3(\partial_x f(x))
\]
with
\[
I_1(f)(x) = P_n^G Q_{N,n,f}^0(x), \quad \quad (3.37)
\]
\[
I_2(f)(x) = \sum_{1 \leq r_1 < \cdots < r_{N+1} \leq n} P_{r_{N+1}+1,r_{N+1}}^G P_{r_{N+1},r_{N+1}}^G \cdots P_{r_1+1,r_1}^G P_{r_1,1}^G Q_{N,r_1,\ldots,r_{N+1}}^{(N+1)} f(x)
\]
\[
I_3(f)(x) = \sum_{m=1}^{N} \sum_{1 \leq r_1 < \cdots < r_m \leq n} P_{r_m+1,1}^G P_{r_m-1,1}^G \cdots P_{r_1+1,1}^G P_{r_1,1}^G Q_{N,r_1,\ldots,r_m}^{(m)} f(x)
\]
and (see (2.36) and (2.45))
\[
Q_{N,r_1,\ldots,r_m}^{(m)} f(x) = \sum_{3 \leq |\alpha| \leq N_m} a_{n}^{\alpha_1,\ldots,\alpha_m}(\alpha) \partial_{\alpha_1,\ldots,\alpha_m} f(x),
\]
\[
Q_{N,n}^{0} f(x) = \sum_{N+1 \leq |\alpha| \leq N(N+2N)} c_{n}(\alpha) \partial_\alpha f(x), \quad \quad (3.38)
\]
\( N_m \) being given in Lemma (2.4). The coefficients which appear above verify
\[
|a_{n}^{\alpha_1,\ldots,\alpha_m}(\alpha)| \leq (C_2^{N+1}(Z))^{m} \quad \text{and} \quad |c_{n}(\alpha)| \leq (C_2^{N+1}(Z)C_{2}(Z))^{N(N+2N)}
\]
(3.39)
We first estimate $I_2(f)$. Let us prove that for every $r_1 < \cdots < r_{N+1}$
\[
\begin{align*}
|P_{r_N+1+n}^{G} P_{r_N+1, r_{N+1}}^{G} \cdots P_{r_1, r_2}^{G} P_{k, r_1}^{G} Q_{r_1, \ldots, r_{N+1}}^{(N+1)} \partial_1 f(x)| \\
\leq \frac{\tilde{C}_1}{n^2(4N+3)} (L_{q+(N+1)(N+3)}(f) 2^{l_{q+(N+1)(N+3)}(f)} e^{-\frac{m^2(r)}{64} \times n} + L_0(f) 2^\rho_0(f)) (1 + |x|)^{l_{q+(N+1)(N+3)}(f)}
\end{align*}
\]  
(3.40)
where
\[
\tilde{C}_1 = (C C_2^{N+1}(Z))^{N+1} C_2^{(N+1)/2}(Z) B_{q+(N+1)(N+3)} \quad \text{with}
\]
\[
B_p = (2^p(f)+1)(1+C_{2p}(f))^2 N^p 2^p(f) \frac{C}{r^{p+1} m(r) d(p+1)^2} \times (1+C_{2p}(f)(Z)) \times C_{8d(p+3)}(Z).
\]

Recall that $\sigma_{r_i} \leq \frac{1}{n} C_2(Z)$. We take $n \geq 4(N+1) C_2(Z)$ so that
\[
\sum_{i=1}^{N+1} \sigma_{r_i} \leq \frac{1}{4} I. 
\]  
(3.41)

Recall that $\sum_{i=1}^{n} \sigma_i = I$. So we distinguish now two cases:

**Case 1:**  
\[
\sum_{i=r_{N+1}+1}^{n} \sigma_i \geq \frac{1}{2} I.
\]  
(3.42)

**Case 2:**  
\[
\sum_{i=1}^{r_{N+1}+1} \sigma_i \geq \frac{1}{2} I.
\]  
(3.43)

We treat Case 1. Notice that all the operators coming on in (3.37) commute so, using also (3.38) we obtain
\[
P_{r_N+1+n}^{G} P_{r_N+1, r_{N+1}}^{G} \cdots P_{r_1, r_2}^{G} P_{k, r_1}^{G} Q_{r_1, \ldots, r_{N+1}}^{(N+1)} \partial_1 f(x)
= \sum_{3 \leq |\alpha| \leq (N+1)(N+3)} a_{r_1, \ldots, r_{N+1}}^{\alpha} \theta_{r_1, \ldots, r_{N+1}}^{\alpha} \partial_{r_1}^{G} \cdots \partial_{r_{N+1}}^{G} \partial_{r_{N+1}+n} f(x).
\]

Using (3.42) and (3.32) with $m = |\gamma| + |\alpha| \leq q + (N+1)(N+3)$ we get
\[
|P_{r_N+1+n}^{G} \partial_{r_1} \partial_{r} f(x)|
\leq A_{q+(N+1)(N+3)} (L_{q+(N+1)(N+3)}(f) 2^{l_{q+(N+1)(N+3)}(f)} e^{-\frac{m^2(r)}{64} \times n} + L_0(f) 2^\rho_0(f)) (1 + |x|)^{l_{q+(N+1)(N+3)}(f)}
\]
with
\[
A_p = \frac{C}{r^{p+1} m(r) d(p+1)^2} \times (1+C_{2p}(f)(Z)) \times C_{8d(p+3)}(Z).
\]

Therefore, we can write
\[
\begin{align*}
L_0(P_{r_N+1+n}^{G} \partial_{r_1} \partial_{r} f) &= A_{q+(N+1)(N+3)} (L_{q+(N+1)(N+3)}(f) 2^{l_{q+(N+1)(N+3)}(f)} e^{-\frac{m^2(r)}{64} \times n} + L_0(f) 2^\rho_0(f)) \\
&L_0(P_{r_N+1+n}^{G} \partial_{r_1} \partial_{r} f) = l_{q+(N+1)(N+3)}(f).
\end{align*}
\]

Now, in the proof of Theorem 2.2 we have proven that
\[
|P_{r_{N-1}+1, r_{N-1}}^{G} \cdots P_{r_1, r_2}^{G} P_{k, r_1}^{G} g(x)| \leq L_0(g)(1+C_{2l_0}(g)) 2^\rho_0(g) (1 + |x|)^{l_0(g)}
\]

27
and following the proof of Lemma 2.4 we have
\[ |\theta_{r_1, \ldots, r_m}^\alpha g(x)| \leq (2^{l_0(g)+1} C_{2(N+3)}^{1/2}(Z)(1 + C_2 l_0(Z))^2)^m L_0(g)(1 + |x|)^{l_0(g)}. \]

So, taking all estimates, we obtain
\[ |P_{r_{N+1}, \ldots, r_{N+1}}^Z P_{r_{N+1}, r_{N+1}}^{G} \ldots P_{r_{1}, r_{1}}^{G} P_{r_{1}, r_{2}}^{G} P_{r_{1}, \ldots, r_{N+1}}^{G} \partial_\gamma f(x)| \leq B_q+(N+1)(N+3) C_{2(N+3)}^{(N+1)/2} \times \]
\[ \times (L_{q+(N+1)(N+3)} f)^{2q+(N+1)(N+3)}(f) e^{-\frac{m_2(r)}{64} x_n} + L_0(f) 2^{l_0(f)} (1 + |x|)^{l_q+(N+1)(N+3)}(f) \]
with
\[ B_p = (2^{l_p(f)+1} C_{2l_p(f)+1})^{N+1} A_p 2^{l_p(f)}. \]

So,
\[ |P_{r_{N+1}, \ldots, r_{N+1}}^Z P_{r_{N+1}, r_{N+1}}^{G} \ldots P_{r_{1}, r_{1}}^{G} P_{r_{1}, \ldots, r_{N+1}}^{G} \partial_\gamma f(x)| \leq \sum_{3 \leq |\alpha| \leq (N+1)(N+3)} |a_{n_1, \ldots, n_{N+1}}^{(r_1, \ldots, r_{N+1})}(\alpha)| B_q+(N+1)(N+3) C_{2(N+3)}^{(N+1)/2} \times \]
\[ \times (L_{q+(N+1)(N+3)} f)^{2q+(N+1)(N+3)}(f) e^{-\frac{m_2(r)}{64} x_n} + L_0(f) 2^{l_0(f)} (1 + |x|)^{l_q+(N+1)(N+3)}(f) \]
\[ \leq \frac{(CC_2^{N+1}(Z))^{N+1}}{n^{\frac{N+3}{2}}} B_q+(N+1)(N+3) C_{2(N+3)}^{(N+1)/2} \times \]
\[ \times (L_{q+(N+1)(N+3)} f)^{2q+(N+1)(N+3)}(f) e^{-\frac{m_2(r)}{64} x_n} + L_0(f) 2^{l_0(f)} (1 + |x|)^{l_q+(N+1)(N+3)}(f), \]
and (3.40) is proved in Case 1.

We deal now with Case 2. We write
\[ P_{r_{N+1}, \ldots, r_{N+1}}^Z P_{r_{N+1}, r_{N+1}}^{G} \ldots P_{r_{1}, r_{1}}^{G} P_{r_{1}, r_{2}}^{G} P_{r_{1}, \ldots, r_{N+1}}^{G} \partial_\gamma f(x) = \sum_{3 \leq |\alpha| \leq (N+1)^2} a_{n_1, \ldots, n_{N+1}}^{(r_1, \ldots, r_{N+1})}(\alpha) \theta_{r_1, \ldots, r_{N+1}}^\alpha f(x). \]

Notice that
\[ P_{r_{N+1}, r_{N+1}}^{G} \ldots P_{r_{1}, r_{1}}^{G} P_{r_{1}, r_{2}}^{G} P_{r_{1}, \ldots, r_{N+1}}^{G} \partial_\gamma \partial_\alpha f(x) = \mathbb{E}(\partial_\gamma \partial_\alpha f(x + G)) \]
where $G$ is a centred Gaussian random variable of variance $\sum_{i=1}^{r_{N+1}} \sigma_i - \sum_{i=1}^{m} \sigma_i \geq \frac{1}{4} I$. So standard integration by parts yields
\[ |P_{r_{N+1}, r_{N+1}}^{G} \ldots P_{r_{1}, r_{1}}^{G} P_{r_{1}, r_{2}}^{G} P_{r_{1}, \ldots, r_{N+1}}^{G} \partial_\gamma \partial_\alpha f(x)| \leq CL_0(f)(1 + |x|)^{l_0(f)}. \]

Now the proof follows as in the previous case. So (3.40) is proved. And, summing over $r_1 < r_2 < \cdots < r_{N+1} \leq n$ we get
\[ |I_2(\partial_\gamma f)(x)| \leq n^{N+1} \frac{\hat{C}_1}{n^{2(N+3)}} (L_{q+(N+1)(N+3)} f)^{2q+(N+1)(N+3)}(f) e^{-\frac{m_2(r)}{64} x_n} + L_0(f) 2^{l_0(f)} (1 + |x|)^{l_q+(N+1)(N+3)}(f) \]
\[ \leq \frac{\hat{C}_1}{n^{2(N+1)}} (L_{q+(N+1)(N+3)} f)^{2q+(N+1)(N+3)}(f) e^{-\frac{m_2(r)}{64} x_n} + L_0(f) 2^{l_0(f)} (1 + |x|)^{l_q+(N+1)(N+3)}(f). \]
Exactly as in Case 2 presented above (using standard integration by parts with respect to the law of Gaussian random variables) we obtain

$$|I_1(\partial_z f)(x)| + |I_3(\partial_z f)(x)| \leq \frac{\bar{C}_1}{n^{2(N+1)}L_0(f)(1 + |x|)^{l_0(f)}}.$$  

So, (3.36) is proved.

**Step 2.** We now come back and we replace $L_q(N+1)(N+3)(f)$ by $L_q(f)$ in (3.36). We will use the regularization lemma. So we fix $\delta > 0$ (to be chosen in a moment) and we write

$$|\mathbb{E}(\partial_z f(S_n(Z)) - \mathbb{E}(\partial_z f(W)\Phi_N(W))| \leq A_\delta(f) + A'_\delta(f) + A''_\delta(f)$$

with

$$A_\delta(f) = |\mathbb{E}(\partial_z f_\delta(S_n(Z)) - \mathbb{E}(\partial_z f_\delta(W)\Phi_N(W))|$$

$$A'_\delta(f) = |\mathbb{E}(\partial_z f(S_n(Z)) - \mathbb{E}(\partial_z f_\delta(S_n(Z))|,$$

$$A''_\delta(f) = |\mathbb{E}(\partial_z f(W)\Phi_N(W)) - \mathbb{E}(\partial_z f_\delta(W)\Phi_N(W))|.$$  

We will use (3.36) for $f_\delta$. Notice that $L_m(f_\delta) \leq c_m L_0(f)\delta^{-m}$, with $c_m = \max_{0 \leq |\alpha| \leq m} |\partial_\alpha \delta(x)|dx$, and $l_m(f) = l_0(f)$. So,

$$A_\delta(f) \leq \frac{C_1}{n^{2(N+1)}}L_0(f)(\frac{1}{\delta q^+(N+1)(N+3)}e^{-\frac{m^2(r)n}{64}} + 1),$$

where

$$C_1 = (CC_2^{N+1}(Z))^{N+1}C_2(N+3)^{2(N+1)(l_0(f)+1)+2(1 + C_2^{l_0(f)}(Z))^{2(N+1)+1}B_{q^+(N+1)(N+3)}$$

with $B_p = \frac{C}{\gamma^m(m)(r)^{(p+1)^2}} \times C_{2d^{p+2}(p+3)}^{8d^{p+2}(p+3)}(Z).$

We use now (3.30) with $x = 0$ and with some $h$ to be chosen in a moment. We then obtain

$$A'_\delta(f) \leq CC^{1/2}_{2l_0(f)}(Z)Q_{h,q}(Z)(L_q(f)\exp \left(-\frac{m^2(r)}{32}\times n\right) + L_0(f)\delta^h)$$

with $Q_{h,q}(Z)$ defined in (3.31). (In order to identify the notation from (3.31) we recall that $q = |\gamma|$ was denoted by $m$ in (3.31) and $h$, which we may choose as we want, was denoted by $q$ in (3.31).) And we also have $A''_\delta(f) \leq CL_0(f)\delta^h$ (the proof is identical to the one of (3.24) but one employs usual integration by parts with respect to the Gaussian law). We put all this together and we obtain

$$|\mathbb{E}(\partial_z f(S_n(Z)) - \mathbb{E}(\partial_z f(W)\Phi_N(W))| \leq \frac{C_1}{n^{2(N+1)}}L_0(f)(\frac{1}{\delta q^+(N+1)(N+3)}e^{-\frac{m^2(r)n}{64}} + 1)$$

$$+ CC^{1/2}_{2l_0(f)}(Z)Q_{h,q}(Z)(L_q(f)e^{-\frac{m^2(r)n}{32}} + L_0(f)\delta^h)$$

We take now $\delta$ such that

$$\delta^h = \frac{1}{\delta q^+(N+1)(N+3)}e^{-\frac{m^2(r)n}{64}}$$

so that

$$\delta^h = e^{-\frac{m^2(r)n}{64} \times \frac{n}{\delta q^+(N+1)(N+3)}} = e^{-\frac{m^2(r)n}{128}}$$
We show the main changes in the estimate of Proposition 3.9. The result in Theorem 3.8 holds without assuming the normalization condition (1.2). In fact, we can state the following

\[ \frac{1}{2} \text{ for } I_2(f) \text{ (for } I_1(f), I_3(f) \text{ the proof is analogous). We split } P_{Z_{N+1}+1,n} = P_{Z_{N+1}+1,n-m} P_{n-m,n} \text{ and we need to have sufficient noise in order that } P_{Z_{N+1}+1,n-m} \text{ gives the regularization effect. Then, the two cases described in (3.42) and (3.43) are replaced now by } \sum_{i=r}^{n-m} \sigma_i \geq \frac{1}{2} I_1 \text{ and } \sum_{i=1}^{N+1} \sigma_i \geq \frac{1}{2} I_1 \text{ respectively. And the condition (3.41) becomes } \sum_{i=1}^{N+1} \sigma_i \leq \frac{1}{2} I_1. \text{ Then the proof follows exactly the same line.} \]

The result in Theorem 3.8 holds without assuming the normalization condition (1.2). In fact, we can state the following

**Proposition 3.9.** Assume that for some \( m < n \) one has \( Y_k \in L(2r, \varepsilon) \) for \( k \leq n-m \) and \( \sum_{k=1}^{n-m} \sigma_k \geq \frac{1}{2} I_1\). Then (3.38) holds true.

**Proof.** The idea is that, since \( \sum_{k=1}^{n-m} \sigma_k \geq \frac{1}{2} I_1 \), the random variables \( Y_k \), \( k \leq n-m \) contain sufficient noise in order to give the regularization effect.

We show the main changes in the estimate of \( I_2(f) \) (for \( I_1(f) \), \( I_3(f) \) the proof is analogous). We split \( P_{Z_{N+1}+1,n} = P_{Z_{N+1}+1,n-m} P_{n-m,n} \) and we need to have sufficient noise in order that \( P_{Z_{N+1}+1,n-m} \) gives the regularization effect. Then, the two cases described in (3.42) and (3.43) are replaced now by

\[ \sum_{i=r}^{n-m} \sigma_i \geq \frac{1}{4} I_1 \text{ and } \sum_{i=1}^{N+1} \sigma_i \geq \frac{1}{4} I_1 \text{ respectively. And the condition (3.41) becomes } \sum_{i=1}^{N+1} \sigma_i \leq \frac{1}{4} I_1. \text{ Then the proof follows exactly the same line.} \]

The result in Theorem 3.8 holds without assuming the normalization condition (1.2). In fact, we can state the following

**Proposition 3.10.** Let \( \sigma_n \) denote the covariance matrix of \( S_n(Z) \) and assume it is invertible. Then (3.38) reads: for a multi-index \( \alpha \) with \( |\alpha| = q \)

\[ \left| \mathbb{E}(\partial_{\alpha} f(S_n(Z))) - \mathbb{E}(\partial_{\alpha} f(S_n^2 W) \Phi^\alpha_N(W)) \right| \leq C \times C_n^\alpha(Z)(\frac{1}{n_{2(N+1)}} L_0(f) + L_q(f)e^{-\frac{m^2(\varepsilon \times \alpha)}{16} n}) \tag{3.44} \]

where \( W \) is a standard Gaussian random variable and \( \Phi^\alpha_N \) is defined in (2.10) using \( \mathbf{Z}_k = \sigma_n^{-1/2} Z_k \) instead of \( Z_k \) (this means that the coefficients \( \Delta_\alpha(k) = \mathbb{E}(Z_k^\alpha) - \mathbb{E}(G_k^\alpha) \) are replaced by \( \mathbf{Z}_\alpha(k) = \mathbb{E}(\mathbf{Z}_k^\alpha) - \mathbb{E}(G_k^\alpha) \)). And \( C_n^\alpha(Z) = (\mathbf{\Lambda}^{\alpha q} / \mathbf{\Lambda}^{-\alpha q}) C_\alpha(Z) \) with \( C_\alpha(Z) \) given in (3.34) and \( \mathbf{\Lambda}^\alpha \) respectively the lower respectively the larger eigenvalue of \( \sigma_n \). Finally \( \mathbf{r} = r(\mathbf{\Lambda}^\alpha / \mathbf{\Lambda}_n^\alpha) \).

**Proof.** For a matrix \( \sigma \in \mathcal{M}_{d \times d} \) and for two multi-indexes \( \alpha = (\alpha_1, \ldots, \alpha_q), \beta = (\beta_1, \ldots, \beta_q) \) we denote \( \sigma^{\alpha, \beta} = \prod_{i=1}^q \sigma^{\alpha_i, \beta_i} \). Suppose that \( \sigma \) is invertible and let \( \gamma = \sigma^{-1} \). For a function \( f : \mathbb{R}^d \to \mathbb{R} \) let \( f_\alpha(x) = f(\alpha x) \). A simple computation shows that

\[ (\partial_{\alpha} f)(\sigma x) = \sum_{|\beta| = |\alpha|} \gamma^{\alpha, \beta} \partial_{\beta} f_\sigma(x). \]
We denote now $Z_k = \sigma_{n}^{-1/2}X_k$ and we note that $S_n(Z) = \sigma_{n}^{-1/2}S_n(Z)$ verifies the normalization condition (1.2). So using (3.33) for $S_n(Z)$ we obtain
\[
E(\partial_\alpha f(S_n(Z))) = E(\partial_\alpha f(\sigma_{n}^{-1/2}S_n(Z))) = \sum_{|\beta|=q} (\sigma_{n}^{-1/2})^{\alpha,\beta} E(\partial_\beta f_{\sigma_{n}^{-1/2}}(S_n(Z)))
\]
\[
= \sum_{|\beta|=q} (\sigma_{n}^{-1/2})^{\alpha,\beta} (E(\partial_\beta f_{\sigma_{n}^{-1/2}}(W)) \Phi_{N}^{\sigma_{n}}(W) + R_{N}^{3}(n))
\]
\[
= E(\partial_\alpha f(\sigma_{n}^{-1/2}W) \Phi_{N}^{\sigma_{n}}(W)) + \sum_{|\beta|=q} (\sigma_{n}^{-1/2})^{\alpha,\beta} R_{N}^{3}(n).
\]
The estimate of $R_N(n)$ follows from the fact that $L_q(f_{\sigma_{n}^{-1/2}}) \leq \sum_{|\beta|=q} (\sigma_{n}^{-1/2})^{\alpha,\beta} \leq C\alpha_{n}^{-q}$. □

Another immediate consequence of Theorem 3.8 is given by the following estimate for an “approximative density” of the law of $S_n(Z)$:

**Corollary 3.11.** Suppose that $n^{(N+1)(1+1/d)}e^{-\frac{n^2(a)}{2d}}/n \leq 1$. Let $\delta_n$ be such that
\[
n^{(N+1)/2d}e^{-\frac{n^2(a)}{16d}}/n \leq \delta_n \leq \frac{1}{n^{1/2}(N+1)}.
\]
Then
\[
\left|E\left(\frac{1}{\delta_n^d} 1_{\{|S_n(Z)-a| \leq \delta_n\}} - \gamma_d(a) \Phi_N(a)\right)\right| \leq \frac{C}{n^{1/2}(N+1)}.
\]
(3.45)

Here $\gamma_d$ is the density of the standard normal law in $\mathbb{R}^d$.

**Proof.** Let $h(x) = \int_{-\infty}^{x_1} dx_1 ... \int_{-\infty}^{x_{d-1}} \frac{1}{\delta_n^d} 1_{\{|x-a| \leq \delta_n\}} dx_d$ so that $\frac{1}{\delta_n^d} 1_{\{|x-a| \leq \delta_n\}} = \partial_{x_1} ... \partial_{x_d} h(x)$. Using Theorem 3.8,
\[
E\left(\frac{1}{\delta_n^d} 1_{\{|S_n(Z)-a| \leq \delta_n\}}\right) = E(\partial_{x_1} ... \partial_{x_d} h(S_n(Z))) = E(\partial_{x_1} ... \partial_{x_d} h(W) \Phi_N(W)) + R_N(n)
\]
\[
= E\left(\frac{1}{\delta_n^d} 1_{\{|W-a| \leq \delta_n\}} \Phi_N(W)\right) + R_N(n)
\]
with
\[
|R_N(n)| \leq C\left(\frac{1}{n^{1/2}(N+1)} + \frac{1}{\delta_n^d} e^{-\frac{n^2(a)}{16d}}/n\right) \leq \frac{C}{n^{1/2}(N+1)}
\]
the last inequality being true by our choice of $\delta_n$. Moreover
\[
E\left(\frac{1}{\delta_n^d} 1_{\{|W-a| \leq \delta_n\}}\right) \Phi_N(W) = \int_{\mathbb{R}^d} \frac{1}{\delta_n^d} 1_{\{|y-a| \leq \delta_n\}} \Phi_N(y) \gamma_d(y) dy
\]
\[
= \Phi_N(a) \gamma_d(a) + R'(n)
\]
with $|R'(n)| \leq \frac{C}{n^{1/2}(N+1)}$ the last inequality being again a consequence of the choice of $\delta_n$. □

We now prove a stronger version of Prohorov’s theorem. We consider a sequence of identical distributed, centred random variables $X_k \in \mathbb{R}^d$ which have finite moments of any order and we look to
\[
S_n(X) = \frac{1}{\sqrt{n}} \sum_{k=1}^{n} X_k.
\]
Following Porhorov we assume that there exist \( m \in \mathbb{N} \) such that
\[
P(X_1 + ... + X_m \in dx) = \mu(dx) + \psi(x)dx
\] (3.46)
for some measurable non-negative function \( \psi \).

**Corollary 3.12.** We assume that (3.46) holds. We fix \( q, N \in \mathbb{N} \). There exists two constants \( 0 < c_* \leq 1 \leq C_* \) (depending on \( N \) and \( q \)) such that the following holds: if
\[
n^{\frac{1}{2}(N+1)}e^{-c_*n} \leq 1
\]
then, for every multi-index \( \gamma \) with \( |\gamma| \leq q \) and for every \( f \in C^q_p(\mathbb{R}^d) \) one has
\[
|\mathbb{E}(\partial_\gamma f(S_n(X))) - \mathbb{E}(\partial_\gamma f(W)\Phi_N(W))| \leq C_*\left( \frac{1}{n^{\frac{1}{2}(N+1)}}L_0(f) + L_q(f)e^{-c_*n} \right)
\] (3.47)

**Proof.** We denote
\[
Y_k = \sum_{i=2km+1}^{2(k+1)m} X_i \quad \text{and} \quad Z_k = \frac{1}{\sqrt{n}} Y_k.
\]
Notice that we may take \( \psi \) in (3.46) to be bounded with compact support. Then \( \psi \ast \psi \) is continuous and so we may find some \( r > 0, \epsilon > 0 \) and \( y \in \mathbb{R}^d \) such that
\[
\psi \ast \psi \geq \epsilon 1_{B_r(y)}.
\]
It follows that
\[
Y_k \in L(2r, \epsilon)
\]
and we may use the previous theorem in order to obtain (3.47) for
\[
n = 2m' \quad \text{with} \quad n' \in \mathbb{N}.
\]
But this is not satisfactory because we claim that (3.47) holds for every \( n \in \mathbb{N} \). This does not follow directly but needs to come back to the proof of Theorem 3.8 and to adapt it in the following way. Suppose that \( 2mn' \leq n < 2m(n' + 1) \). Then
\[
S_n(X) = S_{2mn'}(X) + \frac{1}{\sqrt{n}} \sum_{k=2mn'+1}^{n} X_k = \frac{1}{\sqrt{n}} \sum_{k=1}^{n'} Y_k + \frac{1}{\sqrt{n}} \sum_{k=2mn'+1}^{n} X_k.
\]
Since \( X_k, 2mn' + 1 \leq k \leq n \) have no regularity property, we may not use them in the regularization arguments employed in the proof of Theorem 3.8. But \( Y_k, 1 \leq k \leq n' \) contain sufficient noise in order to achieve the proof (see Remark 3.9). \( \square \)

4 **Examples**

4.1 **An invariance principle related to the local time**

In this section we consider a sequence of independent identically distributed, centred random variables \( Y_k, k \in \mathbb{N} \), with finite moments of any order and we denote
\[
S_n(k, Y) = \frac{1}{\sqrt{n}} \sum_{i=1}^{k} Y_i.
\]
Our aim is to study the asymptotic behaviour of the expectation of
\[
L_n(Y) = \frac{1}{n} \sum_{k=1}^{n} \psi_{\varepsilon_n}(S_n(k, Y)) \quad \text{with} \quad \psi_{\varepsilon_n}(x) = \frac{1}{2\varepsilon_n}1_{\{|x| \leq \varepsilon_n\}}.
\]
So \( L_n(Y) \) appears as the occupation time of the random walk \( S_n(k, Y), k = 1, ..., n \), and consequently, as \( \varepsilon_n \to 0 \), one expects that it has to be close to the local time in zero at time 1, denoted by \( l_1 \), of the Brownian motion. In fact, we prove now that \( \mathbb{E}(L_n(Y)) \to \mathbb{E}(l_1) \) as \( n \to \infty \).
Theorem 4.1. Let \( \varepsilon_n = n^{-\frac{1}{2}(1-\rho)} \) with \( \rho \in (0,1) \). We consider a centred random variable \( Y \in L(r, \varepsilon) \) which has finite moments of any order and we take a sequence \( Y_i, i \in \mathbb{N} \) of independent copies of \( Y \). We define

\[
N(Y) = \max\{2k : E(Y^{2k}) = E(G^{2k})\} - 1 \geq 1
\]

and we denote \( p_{N(Y)} = 8(1 + (N(Y) + 1)(N(Y) + 3))(4 + (N(Y) + 1)(N(Y) + 3)) \). For every \( \eta < 1 \) there exists a constant \( C \) depending on \( r, \varepsilon, \rho, \eta \) and on \( \|Y\|_{p_{N(Y)}} \) such that

\[
\left| E(L_n(Y)) - E(L_n(G)) \right| \leq \frac{C}{n^{\frac{1}{2} + \frac{\eta}{p_{N(Y)}}}}.
\]

The above inequality holds for \( n \) which is sufficiently large in order to have

\[
n^{\frac{1}{2}} \exp \left( - \frac{m^2(r)}{32} \times n^{\eta}\right) \leq \frac{1}{n^{\frac{1}{2}(N(Y)+1)\eta}}.
\]

As a consequence, we have

\[
\lim_{n \to \infty} E(L_n(Y)) = E(l_1),
\]

\( l_1 \) denoting the local time in the point 0 at time 1 of a Brownian motion.

Proof. All over this proof we denote by \( C \) a constant which depends on \( r, \varepsilon, \rho, \eta \) and on \( \|Y\|_{p_{N(Y)}} \) (as in the statement of the lemma) and which may change from a line to another.

Step 1. We take \( k_n = n^{\eta\rho} \). Suppose first that \( k \leq k_n \). We write

\[
E(\psi_{\varepsilon_n}(S_n(k,Y))) = \frac{1}{\varepsilon_n}\left( 1 - P(|S_n(k,Y)| \geq \varepsilon_n) \right)
\]

so that

\[
|E(\psi_{\varepsilon_n}(S_n(k,Y))) - E(\psi_{\varepsilon_n}(S_n(k,G)))| \leq \frac{1}{\varepsilon_n}(P(|S_n(k,Y)| \geq \varepsilon_n) + P(|S_n(k,G)| \geq \varepsilon_n)).
\]

Using Chebyshev’s inequality and Burkholder’s inequality we obtain for every \( p \geq 2 \)

\[
P(|S_n(k,Y)| \geq \varepsilon_n) = P\left( \left| \sum_{i=1}^{k} Y_i \right| \geq \varepsilon_n \sqrt{n} \right) \leq \frac{1}{(\varepsilon_n \sqrt{n})^p} E\left( \left| \sum_{i=1}^{k} Y_i \right|^p \right)
\]

\[
\leq \frac{C}{(\varepsilon_n \sqrt{n})^p} \left( \sum_{i=1}^{k} \|Y_i\|_p^2 \right)^{p/2} \leq \frac{Ck^{p/2}}{(\varepsilon_n \sqrt{n})^p} = C \frac{k^p}{\varepsilon_n^p} \times \left( \frac{k}{n} \right)^{p/2}.
\]

And the same estimate holds with \( Y_i \) replaced by \( G_i \). We conclude that

\[
\left| E\left( \frac{1}{n} \sum_{k=1}^{k_n} \psi_{\varepsilon_n}(S_n(k,Y)) \right) - E\left( \frac{1}{n} \sum_{k=1}^{k_n} \psi_{\varepsilon_n}(S_n(k,G)) \right) \right| \leq \frac{C}{\varepsilon_n^p} \times \frac{1}{n} \sum_{k=1}^{k_n} \left( \frac{k}{n} \right)^{p/2}
\]

\[
\leq \frac{C}{\varepsilon_n^p+1} \times \int_{0}^{k_n/n} x^{p/2} dx = \frac{C}{\varepsilon_n^p+1} \times \left( \frac{k_n}{n} \right)^{p/2+1}
\]

\[
= \frac{C}{n^{\frac{p}{2}(1-\eta)+\frac{1}{2}(1-\eta)\rho}} \leq \frac{C}{n^{\frac{p}{2}(1-\eta)}}.
\]
We take \( p = \frac{1 + \rho N(Y)}{\rho (1 - \eta)} \) and we obtain

\[
\left| \mathbb{E}\left( \frac{1}{n} \sum_{k=1}^{k_n} \psi_{\varepsilon_n}(S_n(k, Y)) \right) - \mathbb{E}\left( \frac{1}{n} \sum_{k=1}^{k_n} \psi_{\varepsilon_n}(S_n(k, G)) \right) \right| \leq \frac{C}{n^{\frac{1}{2} + \frac{N(Y)}{2} \eta \rho}}.
\]

**Step 2.** We fix now \( k \geq k_n \) and we apply our Edgeworth development (see (3.33)) to

\[
\frac{1}{\sqrt{k}} \sum_{i=1}^{k} Y_i = \sum_{i=1}^{k} Z_i, \quad \text{where} \quad Z_i = \frac{1}{\sqrt{k/2}} Y_i.
\]

In particular the constants \( C_p(Z) \) defined in (2.41) are given by \( C_p(Z) = k^{p/2} \max_i \mathbb{E}(|Z_i|^p) = \|Y\|^p \).

We denote

\[
h_{\alpha,n}(x) = \int_{-\infty}^{\alpha x} \psi_{\varepsilon}(y)dy = h_{1,n}(\alpha x),
\]

(4.4)

This gives \( \psi_{\varepsilon}(x) = h'_{1,n}(x) \) and \( h'_{\alpha,n}(x) = \alpha h'_{1,n}(\alpha x) \). Moreover, \( \|h_{\alpha,n}\|_\infty \leq 1 \) and \( \|h'_{\alpha,n}\|_\infty \leq |\alpha|/\varepsilon_n \), so that

\[
L_0(h_{\alpha,n}) = 1 \quad \text{and} \quad L_1(h_{\alpha,n}) = |\alpha| \times \frac{1}{\varepsilon_n}.
\]

We now write

\[
\mathbb{E}(\psi_{\varepsilon}(S_n(k, Y))) = \mathbb{E}(h'_{1,n}(S_n(k, Y))) = \mathbb{E}\left( h'_{1,n}\left( \sqrt{\frac{k}{n}} \sum_{i=1}^{k} Y_i \right) \right)
\]

\[
= \frac{\sqrt{n}}{k} \mathbb{E}\left( h'_{\frac{1}{\sqrt{\frac{k}{n}}}}\left( \sqrt{\frac{k}{n}} \sum_{i=1}^{k} Y_i \right) \right).
\]

We will use (3.33) with \( f = h_{1,n}(\sqrt{\frac{k}{n}}) \) and \( \partial_\gamma \) will be the first order derivative. Then, by (3.33) with \( N = N(Y) \)

\[
\mathbb{E}(\psi_{\varepsilon}(S_n(k, Y))) = \sqrt{\frac{n}{k}} \left( \mathbb{E}\left( h'_{\sqrt{\frac{k}{n}}} \left( W_1 \Phi_{N(Y)}(W_1) \right) \right) + R_{N(Y)}(k) \right)
\]

with

\[
|R_{N(Y)}(k)| \leq \frac{C}{k^{(N(Y)+1)/2}} L_0(h_{\sqrt{\frac{k}{n}}}) + C L_1(h'_{\sqrt{\frac{k}{n}}}) \exp\left( - \frac{m^2(r)}{32} \times k \right)
\]

\[
\leq \frac{C}{k^{(N(Y)+1)/2}} + C \sqrt{\frac{k}{n}} \times \frac{1}{\varepsilon_n} \exp\left( - \frac{m^2(r)}{32} \times k \right).
\]

Here \( C \) is the constant from (3.33) defined in (3.34). Notice that by (4.2), for \( k \geq k_n = n^{\eta \rho} \) one has

\[
\sqrt{\frac{k}{n}} \times \frac{1}{\varepsilon_n} \exp\left( - \frac{m^2(r)}{32} \times k \right) \leq \frac{1}{n^{\frac{1}{2} + (N(Y)+1)/2}} = \frac{1}{k^{(N(Y)+1)/2}} \leq \frac{C}{k^{(N(Y)+1)/2}},
\]

\[34\]
so that \( |R_{N(Y)}(k)| \leq Ck^{-(N(Y)+1)/2} \). Then
\[
\left| \sum_{k=k_n}^n \sqrt{\frac{k}{n}} R_{N(Y)}(k) \frac{1}{n} \right| \leq \frac{C}{n^{(N(Y)+1)/2}} \sum_{k=k_n}^n \frac{1}{(k/n)^{1+N(Y)/2}} \times \frac{1}{n}
\leq \frac{C}{n^{(N(Y)+1)/2}} \int_{k_n/n}^1 \frac{ds}{s^{1+N(Y)/2}}
= \frac{C}{n^{(N(Y)+1)/2}} \left( n/k_n \right)^{N(Y)/2} = \frac{C}{n^{1+N(Y)/2}}.
\]

We recall now that (see (2.15))
\[
\Phi_{N(Y)}(x) = 1 + \sum_{l=1}^{N(Y)} H_l(x)
\]
with \( H_l(x) \) linear combinations of Hermite polynomials (see (2.10) and (2.14)). Notice that if \( l \) is odd then \( \Gamma_1 \) is a linear combination of differential operators of odd order (see the definition of \( \Lambda_m \) in (2.9)). So \( H_l(x) \) is an odd function (as a linear combination of Hermite polynomials of odd order) so that \( \psi_{\varepsilon_n} \times H_l(x) \) is also an odd function. Since \( W_1 \) and \( -W_1 \) have the same law, it follows that
\[
\mathbb{E}\left( \psi_{\varepsilon_n} \left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} W_1 \right) H_l(W_1) \right) = \mathbb{E}\left( \psi_{\varepsilon_n} \left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} (-W_1) \right) H_l(-W_1) \right)
= -\mathbb{E}\left( \psi_{\varepsilon_n} \left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} W_1 \right) H_l(W_1) \right)
\]
and consequently
\[
\sqrt{\frac{n}{k}} \times \mathbb{E}\left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} (W_1) H_l(W_1) \right) = \mathbb{E}\left( \psi_{\varepsilon_n} \left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} W_1 \right) H_l(W_1) \right) = 0.
\]
Moreover, by the definition of \( N(Y) \), for \( 2l \leq N(Y) \) we have \( \mathbb{E}(Y^{2l}) = \mathbb{E}(G_{2l}) \) so that \( H_{2l} = 0 \). We conclude that
\[
\sqrt{\frac{n}{k}} \mathbb{E}\left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} (W_1) \Phi_{N(Y)}(W_1) \right) = \sqrt{\frac{n}{k}} \mathbb{E}\left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} (W_1) \right) = \mathbb{E}\left( \psi_{\varepsilon_n} \left( \frac{\sqrt{\frac{k}{n}}}{\sqrt{\sum_{n,l}^N}} W_1 \right) \right) = \mathbb{E}(\psi_{\varepsilon_n}(S_n(k, G))).
\]

We put now together the results from the first and the second step and we obtain (4.1).

**Step 3.** We prove (4.3). Recall first the representation formula
\[
\mathbb{E}\left( \int_0^1 \psi_{\varepsilon_n}(W_s) ds \right) = \mathbb{E}\left( \int \psi_{\varepsilon_n}(a) dt^0_a da \right),
\]
where \( t^0_a \) denotes the local time in \( a \in \mathbb{R} \) at time 1, so that \( l_1 = t^0_1 \). Since \( a \mapsto l^0_a \) is Hölder continuous of order \( \frac{\rho'}{2} \) for every \( \rho' < 1 \), we obtain
\[
\left| \mathbb{E}\left( \int_0^1 \psi_{\varepsilon_n}(W_s) ds \right) - \mathbb{E}(l^0_1) \right| \leq \mathbb{E}(l^0_1) \leq \varepsilon_n^{\rho'/2} = \frac{1}{n^{\rho'(N(Y)+1)/2}}.
\]

We prove now that, for every \( \rho' < 1 \) and \( n \) large enough,
\[
\left| \mathbb{E}\left( \int_0^1 \psi_{\varepsilon_n}(W_s) ds \right) - \mathbb{E}(L_n(G)) \right| \leq \frac{C}{n^{\rho'(N(Y)+1)/2}}.
\]
To begin we notice that \( S_n(k, G) \) has the same law as \( W_{k/n} \), so that we write

\[
E \left( \int_0^1 \psi_{\varepsilon_n}(W_s) ds \right) - E(L_n(G)) = E \left( \sum_{k=1}^n \delta_k \right)
\]

with

\[
\delta_k = \int_{k/n}^{(k+1)/n} (\psi_{\varepsilon_n}(W_s) - \psi_{\varepsilon_n}(W_{k/n})) ds.
\]

As above, we take \( k_n = n^\rho \eta \) and for \( k \leq k_n \), we have

\[
E(\delta_k) = -\frac{1}{2\varepsilon_n} \int_{k/n}^{(k+1)/n} (P(|W_s| \geq \varepsilon_n) - P(|W_{k/n}| \geq \varepsilon_n)) ds.
\]

Since \( P(|W_s| \geq \varepsilon_n) \leq C \exp(-\frac{\varepsilon^2}{2s}) \), this immediately gives

\[
|E(\delta_k)| \leq \frac{C}{n\varepsilon_n} \exp \left( -\frac{1}{2} \frac{\varepsilon^2}{n} \times \frac{n}{k+1} \right) \leq \frac{C}{n\varepsilon_n} \exp \left( -\frac{1}{2} \frac{\varepsilon^2}{n} \times \frac{n}{k_n+1} \right) = \frac{C}{n\varepsilon_n} \exp \left( -\frac{1}{2} n^\rho (1-\eta) \right)
\]

so that

\[
\sum_{k=1}^{k_n} |E(\delta_k)| \leq \frac{C}{\varepsilon_n} \exp \left( -\frac{1}{8} n^\rho (1-\eta) \right) \leq \frac{C}{n^{1/2}},
\]

for \( n \) large enough.

We consider now the case \( k \geq k_n \). Using a formal computation, by applying the standard Gaussian integration by parts formula, we write

\[
E(\psi_{\varepsilon_n}(W_s) - \psi_{\varepsilon_n}(W_{k/n})) = \frac{1}{2} \int_k^s E(\psi_{\varepsilon_n}''(W_v)) dv = \frac{1}{2} \int_k^s E(\psi_{\varepsilon_n}''(\sqrt{v}W_{1})) dv
\]

\[
= \int_{k/n}^{s} E(h_{1,n}(\sqrt{v}W_{1})H_3(W_1)) dv = \int_{k/n}^{s} \frac{1}{2v^{3/2}} E(h_{1,n}(\sqrt{v}W_{1})H_3(W_1)) dv,
\]

in which we have used \([4.4]\) and where \( H_3 \) denotes the third Hermite polynomial. The above computation is formal because \( \psi_{\varepsilon_n} \) is not differentiable. But, since the first and the last term in the chain of equalities depends on \( \psi_{\varepsilon_n} \) only (and not on the derivatives) we may use regularization by convolution in order to do it rigorously. Notice also that the first equality is obtained using Ito’s formula and the last one is obtained using integration by parts. It follows that

\[
|E(\delta_k)| \leq \int_{k/n}^{(k+1)/n} ds \int_k^s \frac{1}{2v^{3/2}} E(h_{1,n}(\sqrt{v}W_{1})|H_3(W_1)) dv \leq \frac{C}{n} \int_{k/n}^{(k+1)/n} \frac{1}{v^{3/2}} dv
\]

and consequently

\[
\sum_{k=k_n}^{n} |E(\delta_k)| \leq \frac{C}{n} \int_{k_n/n}^{1} \frac{1}{v^{3/2}} dv \leq \frac{C}{n^{1/2}},
\]

So \([4.6]\) is proved, and this together with \([4.5]\) and \([4.1]\), give \([4.3] \). \( \square \)
4.2 Convergence in distribution norms

In this section we prove that, under some supplementary regularity assumptions on the laws of $Z_k$, $k \in \mathbb{N}$, Theorem 3.8 implies that the density of the law of $S_n(Z)$ converges in distribution norms to the Gaussian density. We write

$$Z_k = \frac{C_k}{\sqrt{n}} Y_k$$

and we denote $\sigma_k = C_k C_k^*$. We assume that

$$0 < \underline{\sigma} \leq \sigma_k \leq \overline{\sigma} < \infty, \quad \text{and} \quad \sup_k \| Y_k \|^p_p < \infty. \quad (4.7)$$

In particular each $\sigma_k$ is invertible. We denote $\gamma_k = \sigma_k^{-1}$. Notice that the normalization condition is

$$\frac{1}{n} \sum_{k=1}^n \mathbb{E}(Z_k^i Z_k^j) = 1_{i=j}.$$ 

For a function $f \in C^1(\mathbb{R}^d)$ and for $k \in \mathbb{N}$ we denote

$$m_{1,k}(f) = \int_{\mathbb{R}^d} (1 + |x|^2) |\nabla f(x)| \, dx.$$ 

**Proposition 4.2. A.** We fix $q \in \mathbb{N}$ and we also fix a polynomial $P$. Suppose that $Y_i \in \mathcal{L}(r, \varepsilon)$, $i \in \mathbb{N}$ and (4.7) holds. Moreover we suppose that

$$\mathbb{P}(Y_i \in dy) = p_Y(y)dy \quad \text{with} \quad p_Y \in C^1(\mathbb{R}^d) \quad \text{for every} \quad i = 1, \ldots, q. \quad (4.8)$$

There exist some constants $c \in (0, 1)$ (depending on $r$ and on $\varepsilon$) and $C_q(P) \geq 1$ (depending on $q, \underline{\sigma}, \overline{\sigma}$ and on $P$) such that, if $n(q+1)^2 e^{-cn} \leq 1$, then, for every $f \in C^q_0(\mathbb{R}^d)$, and every multi-index $\alpha$ with $|\alpha| \leq q$

$$|\mathbb{E}(P(S_n(Z)) \partial_\alpha f(S_n(Z)) - \mathbb{E}(P(S_n(G)) \partial_\alpha f(S_n(G)))| \leq \frac{C_q(P)}{\sqrt{n}} \prod_{i=1}^q m_{1,0,0}(f)+\ell_{0}(P)(p_Y) \times L_0(f). \quad (4.9)$$

**B.** Moreover, if $p_{S_n}$ is the density of the law of $S_n(Z)$ then, if $n^{(d+q+1)/2} e^{-cn} \leq 1$, we have

$$\sup_{x \in \mathbb{R}^d} |P(x)(\partial_\alpha p_{S_n}(x) - \partial_\alpha \gamma(x))| \leq \frac{C_{q+d}(P)}{\sqrt{n}} \prod_{i=1}^{q+d} m_{1,0,0}(f)+\ell_{0}(P)(p_Y) \quad (4.10)$$

where $\gamma$ is the density of the standard normal law in $\mathbb{R}^d$.

**Proof A.** We proceed by recurrence on the degree $k$ of the polynomial $P$. First we assume that $k = 0$ (so that $P$ is a constant) and we prove (4.9) for every $q \in \mathbb{N}$. We write

$$S_n(Z) = \frac{1}{\sqrt{n}} \sum_{i=1}^n C_i Y_i = \frac{1}{\sqrt{n}} \sum_{i=1}^q C_i Y_i + S_n^{(q)}(Z).$$

with

$$S_n^{(q)}(Z) = \frac{1}{\sqrt{n}} \sum_{i=q+1}^n C_i Y_i.$$
Then we define
\[ g(x) = \mathbb{E}\left( f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{q} C_i Y_i + x \right) \right) \]
and we have
\[ \mathbb{E}(\partial \alpha f(S_n(Z))) = \mathbb{E}(\partial \alpha g(S_n^{(q)}(Z))). \]
Now using (4.11) with \( N = 0 \) for \( S_n^{(q)}(Z) \) we get
\[ \mathbb{E}(\partial \alpha g(S_n^{(q)}(Z))) = \mathbb{E}(\partial \alpha g(S_n^{(q)}(G))) + R_n = \mathbb{E}\left( \partial \alpha f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{q} C_i Y_i + S_n^{(q)}(G) \right) \right) + R_n \]
with
\[ |R_n| \leq C\left( \frac{1}{\sqrt{n}} L_0(g) + e^{-cn} L_q(g) \right). \]
Let us estimate \( L_q(g) \). We recall that \( \gamma_i = \sigma_i^{-1} \). For \( \alpha = (\alpha_1, ..., \alpha_q) \) we have
\[ (\partial \alpha)\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{n} C_i y_i + x \right) = \sum_{\beta_1, ..., \beta_q=1}^{d} n^{q/2} \left( \prod_{i=1}^{q} (\gamma_i C_i)^{\alpha_i, \beta_i} \right) \times \partial y_{\beta_1} \cdots \partial y_{\beta_q} \left( f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{n} C_i y_i + x \right) \right) \]
in which we have assumed that the \( Y_i \)'s take values in \( \mathbb{R}^m \). So
\[ \partial \alpha g(x) = \mathbb{E}\left( (\partial \alpha) f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{q} C_i Y_i + x \right) \right) \]
\[ = n^{q/2} \sum_{\beta_1, ..., \beta_q=1}^{m} \left( \prod_{i=1}^{q} (\gamma_i C_i)^{\alpha_i, \beta_i} \right) \int_{\mathbb{R}^m} \partial y_{\beta_1} \cdots \partial y_{\beta_q} \left( f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{n} C_i y_i + x \right) \right) \prod_{i=1}^{q} p_{Y_i}(y_i) dy_1 \cdots dy_q \]
\[ = (-1)^q n^{q/2} \sum_{\beta_1, ..., \beta_q=1}^{m} \left( \prod_{i=1}^{q} (\gamma_i C_i)^{\alpha_i, \beta_i} \right) \int_{\mathbb{R}^m} f\left( \frac{1}{\sqrt{n}} \sum_{i=1}^{n} C_i y_i + x \right) \prod_{i=1}^{q} \partial y_{\beta_i} p_{Y_i}(y_i) dy_1 \cdots dy_q. \]
It follows that
\[ |\partial \alpha g(x)| \leq C n^{q/2} L_0(f) \int_{\mathbb{R}^q} (1 + |x|) \left| \sum_{i=1}^{q} |y_i| \right| f_0(f) \prod_{i=1}^{q} \left| \nabla p_{Y_i}(y_i) \right| dy_1 \cdots dy_q \]
\[ \leq C n^{q/2} L_0(f)(1 + |x|) f_0(f) \prod_{i=1}^{q} m_{1, f_0(f)}(p_{Y_i}). \]
We conclude that \( l_q(g) = l_0(f) \) and \( L_q(g) \leq C n^{q/2} L_0(f) \prod_{i=1}^{q} m_{1, f_0(f)}(p_{Y_i}). \) The same is true for \( q = 0 \) and so (4.12) gives
\[ |R_n| \leq C L_0(f) \prod_{i=1}^{q} m_{1, f_0(f)}(p_{Y_i}) \left( \frac{1}{\sqrt{n}} + n^{q/2} e^{-cn} \right) \leq C L_0(f) \prod_{i=1}^{q} m_{1, f_0(f)}(p_{Y_i}) \times \frac{1}{\sqrt{n}} \]
the last inequality being true if \( n^{q/2} e^{-cn} \leq n^{-1/2} \).
So (4.11) says that we succeed to replace \( Y_i, q + 1 \leq i \leq n \) by \( G_i, q + 1 \leq i \leq n \) and the price to be paid is \( C L_0(f) \prod_{i=1}^{q} m_{1, f_0(f)}(p_{Y_i}) \times \frac{1}{\sqrt{n}}. \) Now we can do the same thing and replace \( Y_i, 1 \leq i \leq q \) by \( G_i, 1 \leq i \leq q \) and the price will be the same (here we use \( C_i G_i, i = q + 1, ..., 2q \) instead of \( C_i Y_i, i = 1, ..., q \)). So (4.9) is proved for polynomials \( P \) of degree \( k = 0 \).
We assume now that (4.9) holds for every polynomials of degree less or equal to \( k - 1 \) and we prove it for a polynomial \( P \) of order \( k \). We have

\[
\partial_\alpha (P \times f) = \sum_{(\beta, \gamma) = \alpha} \partial_\beta P \times \partial_\gamma f
\]

so that

\[
P \times \partial_\alpha f = \partial_\alpha (P \times f) - \sum_{|\beta| = 1} \partial_\beta P_k \times \partial_\gamma f.
\]

Since \(|\beta| \geq 1\) the polynomial \( \partial_\beta P \) has degree at most \( k - 1 \). Then the recurrence hypothesis ensures that (4.9) holds for \( \partial_\beta P \times \partial_\gamma f \). Moreover, using again (4.9) for \( g = P \times f \) we obtain (4.9) in which \( l_0(g) \leq L_0(P)l_0(f) \) and \( l_0(g) \leq l_0(P) + l_0(f) \) appear. So A. is proved.

Let us prove B. We denote \( f_x(y) = \prod_{i=1}^d 1_{x_i \in (y, \infty)}(y) \) and, for a multi-index \( \alpha = (\alpha_1, ..., \alpha_q) \) we denote \( \overline{\alpha} = (\alpha_1, ..., \alpha_q, 1, ..., d) \). Then, using a formal computation (which may be done rigourously by means of a regularization procedure) we obtain

\[
P(x)\partial_\alpha p_s(x) = \int \delta_0(y - x) P(y)\partial_\alpha p_s(y) dy
\]

\[
= (-1)^q \sum_{(\beta, \gamma) = \alpha} \int \partial_\beta \delta_0(y - x) \partial_\gamma P(y) p_s(y) dy
\]

\[
= (-1)^q \sum_{(\beta, \gamma) = \alpha} \int \delta_f f_x(y) \partial_\gamma P(y) p_s(y) dy
\]

\[
= (-1)^q \sum_{(\beta, \gamma) = \alpha} E(\partial_\beta f_x(S_n(Z))\partial_\gamma P(S_n(Z))).
\]

A similar computation holds with \( S_n(Z) \) replaced by \( S_n(G) \). So we have

\[
|P(x)(\partial_\alpha p_s(x) - \partial_\alpha^v(x))|
\]

\[
\leq \sum_{(\beta, \gamma) = \alpha} \left| E(\partial_\beta f_x(S_n(Z))\partial_\gamma P(S_n(Z))) - E(\partial_\beta f_x(S_n(G))\partial_\gamma P(S_n(G))) \right|
\]

\[
\leq C_{q+d}(P) \frac{q+d}{\sqrt{n}} \prod_{i=1} \left( m_{1, l_0(f) + l_0(P)}(P Y_i) \right)
\]

the last inequality being a consequence of (4.9). □

**Remark 4.3.** We would like to obtain Edgeworth expansions as well – but there is a difficulty: when we use the expansion for \( S_n^{(q)}(Z) \) we are in the situation when the covariance matrix of \( S_n^{(q)}(Z) \) is not the identity matrix. So the coefficients of the expansion are computed using a correction (see the definition of \( \Delta_k \) in the Remark 3.10). And this correction produces an error of order \( n^{-1/2} \). This means that we are not able to go beyond this level (at least without supplementary technical effort).

**A Computation of the first three coefficients**

We explicitly write the expression of \( \Gamma_k \) for \( k = 1, 2, 3 \) (for larger values of \( k \) the term \( \Gamma_k \) is difficult to explicitly compute). Recall formulas (2.10) for \( \Gamma_k \) and formula (2.9) for the set \( \Lambda_{m,k} \) appearing in (2.10).
Case $k = 1$. Then $m = 1$ and $l = 3, l' = 0$. So the first order terms are given by

$$\Gamma_1 = \sum_{r=1}^{n} \frac{1}{6} D_r^{(3)} = \frac{1}{6} \sum_{|\alpha| = 3} \sum_{r=1}^{n} \Delta_\alpha(r) \partial_\alpha.$$ 

Case $k = 2$. Then $m = 1$ or $m = 2$. Suppose first that $m = 1$. Then we need that $l + 2l' = k + 2m = 4$. This means that we have $l = 4, l' = 0$. The corresponding term is

$$\frac{1}{24} \sum_{r=1}^{n} D_r^{(4)} = \frac{1}{24} \sum_{|\alpha| = 4} \sum_{r=1}^{n} \Delta_\alpha(r) \partial_\alpha.$$ 

Suppose now that $m = 2$. Then we need that $l_1 + l_2 + 2(l_1' + l_2') = k + 2m = 6$. The only possibility is $l_1 = l_2 = 3, l_1' = l_2' = 0$ and the corresponding term is

$$\frac{1}{36} \sum_{0 \leq r_1 < r_2 \leq n} D_{r_1}^{(3)} D_{r_2}^{(3)} = \frac{1}{36} \sum_{|\alpha| = 3, |\beta| = 3} \sum_{0 \leq r_1 < r_2 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \partial_\alpha \partial_\beta.$$ 

We conclude that

$$\Gamma_2 = \frac{1}{24} \sum_{|\alpha| = 4} \sum_{r=1}^{n} \Delta_\alpha(r) \partial_\alpha + \frac{1}{36} \sum_{|\alpha| = 3, |\beta| = 3} \sum_{0 \leq r_1 < r_2 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \partial_\alpha \partial_\beta.$$ 

caso iid

$$\Gamma_2 = \frac{1}{24} \sum_{|\alpha| = 4} n \times \frac{1}{n^2} \Delta_\alpha \partial_\alpha + \frac{1}{36} \sum_{|\alpha| = 3, |\beta| = 3} \sum_{0 \leq r_1 < r_2 \leq n} \frac{n^2 - n}{2} \times \frac{1}{n^3} \Delta_\alpha \Delta_\beta \partial_\alpha \partial_\beta.$$ 

Case $k = 3$. $m = 1$. We need that $l + 2l' = k + 2m = 5$. So $l = 3, l' = 1$ or $l = 5, l' = 0$. The term corresponding to $l = 3, l' = 1$ is

$$- \frac{1}{12} \sum_{r=1}^{n} D_r^{(3)} L_{r,r} = - \frac{1}{12} \sum_{r=1}^{n} \Delta_\alpha(r) \partial_\alpha \sum_{i,j=1}^{d} \alpha_r^{i,j} \partial_i \partial_j$$

$$= - \frac{1}{12} \sum_{|\alpha| = 3} \sum_{i,j=1}^{d} \sum_{r=1}^{n} \Delta_\alpha(r) \alpha_r^{i,j} \partial_i \partial_j.$$ 

and the term corresponding to $l = 5, l' = 0$ is

$$\sum_{r=1}^{n} \frac{1}{5!} D_r^{(5)} = \frac{1}{5!} \sum_{|\alpha| = 5} \sum_{r=1}^{n} \Delta_\alpha(r) \partial_\alpha$$

$m = 2$. We need $l_1 + l_2 + 2(l_1' + l_2') = k + 2m = 3 + 4 = 7$. The only possibility is $l_1 = 3, l_2 = 4, l_1' = l_2' = 0$ and $l_1 = 4, l_2 = 3, l_1' = l_2' = 0$. The corresponding term is

$$2 \sum_{0 \leq r_1 < r_2 < r_3 \leq n} \frac{1}{3!} D_{r_1}^{(3)} \frac{1}{4!} D_{r_2}^{(4)} = \frac{2}{3!} \sum_{|\alpha| = 3} \sum_{|\beta| = 4} \sum_{0 \leq r_1 < r_2 < r_3 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \partial_\alpha \partial_\beta.$$ 

$m = 3$. We need $l_1 + l_2 + l_3 + 2(l_1' + l_2' + l_3') = k + 2m = 3 + 6 = 9$. The only possibility is $l_1 = l_2 = l_3 = 3, l_1' = l_2' = l_3' = 0$ and the corresponding term is

$$\frac{1}{6^3} \sum_{0 \leq r_1 < r_2 < r_3 \leq n} D_{r_1}^{(3)} D_{r_2}^{(3)} D_{r_3}^{(3)} = \frac{1}{6^3} \sum_{|\alpha| = 3} \sum_{|\beta| = 3} \sum_{|\gamma| = 3} \sum_{0 \leq r_1 < r_2 < r_3 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \Delta_\gamma(r_3) \partial_\alpha \partial_\beta \partial_\gamma.$$ 

40
We conclude that

\[
\Gamma_3 = \frac{1}{5!} \sum_{|\alpha|=5}^{n} \sum_{r=1}^{d} \Delta_\alpha(r) \partial_\alpha - \frac{1}{12} \sum_{|\alpha|=3}^{d} \sum_{i,j=1}^{n} \Delta_\alpha(r) \sigma_{r^i,j} \partial_\alpha \partial_i \partial_j \\
+ \frac{2}{3!4!} \sum_{|\alpha|=3}^{d} \sum_{|\beta|=4}^{d} \sum_{0 \leq r_1 < r_2 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \partial_\alpha \partial_\beta \\
+ \frac{1}{6^3} \sum_{|\alpha|=3}^{d} \sum_{|\beta|=3}^{d} \sum_{|\gamma|=3}^{d} \sum_{0 \leq r_1 < r_2 < r_3 \leq n} \Delta_\alpha(r_1) \Delta_\beta(r_2) \Delta_\gamma(r_3) \partial_\alpha \partial_\beta \partial_\gamma.
\]

\[\Box\]

\section{A Backward Taylor formula}

We consider a non-negative definite square matrix \(\sigma \in \mathcal{M}_{d \times d}\) and we write it as \(\sigma = C \times C^*\), with \(C \in \mathcal{M}_{d \times d}\) (so \(C = \sigma^{1/2}\)). And we denote by \(L_\sigma\) the Laplace operator associated to \(\sigma\):

\[L_\sigma f = \sum_{i,j=1}^{d} \sigma^{i,j} \partial_i \partial_j f.\]

We also consider a \(d\)-dimensional Brownian motion \(W = (W^1, \ldots, W^d)\).

\textbf{Lemma B.1.} Set \(L_\sigma = \sum_{i,j=1}^{d} \sigma^{i,j} \partial_i \partial_j\) and let \(C\) denote a matrix such that \(CC^T = \sigma\). Then for every \(k \in \mathbb{N}\), \(k \geq 0\), and \(g \in C^2_b(\mathbb{R}^d)\) one has

\[
g(0) = \mathbb{E}(CW_1) + \sum_{\ell=1}^{k} \frac{(-1)^\ell}{2^{\ell} \ell!} \mathbb{E}(L_\sigma^\ell g(CW_1)) + \frac{(-1)^{k+1}}{2^{k+1} k!} \int_0^1 s^k \mathbb{E}(L_\sigma^{k+1} g(CW_s))ds, \tag{B.1}
\]

in which \(W\) denotes a standard Brownian motion in \(\mathbb{R}^d\).

\textbf{Proof.} Set \(X_t = CW_t\). By Itô’s formula, one has \(\mathbb{E}(g(X_t)) = \mathbb{E}(g(X_0)) + \frac{1}{2} \int_0^t \mathbb{E}(L_\sigma g(X_s))ds\), so we can write

\[
\mathbb{E}(g(X_t)) = \mathbb{E}(g(X_0)) - \frac{1}{2} \int_0^1 \mathbb{E}(L_\sigma g(X_s))ds. \tag{B.2}
\]

Taking \(t = 0\), this gives

\[
g(0) = \mathbb{E}(g(X_0)) - \frac{1}{2} \int_0^1 \mathbb{E}(L_\sigma g(X_s))ds.
\]

We now iterate the above equality. First, we have

\[
g(0) = \mathbb{E}(g(X_1)) - \frac{1}{2} \mathbb{E}(L_\sigma g(X_1)) - \frac{1}{2} \int_0^1 \left[ \mathbb{E}(L_\sigma g(X_s)) - \mathbb{E}(L_\sigma g(X_0)) \right]ds
\]

and by using (B.2) we get

\[
g(0) = \mathbb{E}(g(X_1)) - \frac{1}{2} \mathbb{E}(L_\sigma g(X_1)) + \frac{1}{4} \int_0^1 ds \int_s^1 \mathbb{E}(L_\sigma^2 g(W_u))du
\]

\[
= \mathbb{E}(g(X_1)) - \frac{1}{2} \mathbb{E}(L_\sigma g(X_1)) + \frac{1}{4} \int_0^1 u \mathbb{E}(L_\sigma^2 g(X_u))du.
\]

By proceeding in the iteration, statement (B.1) follows. \(\Box\)
We consider now a sequence of independent centred Gaussian random variables $G_k$ with covariance matrix $\sigma_k$ and we denote $S_p = \sum_{k=1}^p G_k$. Moreover, for a matrix $\sigma \in M_{d \times d}$ we define the operators

$$h_{N,\sigma}^0 \phi(x) = \phi(x) + \sum_{l=1}^N (-1)^l \frac{1}{2^l l!} L_l^\sigma \phi(x) \quad h_{N,\sigma}^1 \phi(x) = \left( \frac{-1}{2^{N+1} N!} \right) \int_0^1 s^N E(L_{\sigma}^{N+1} \phi(x + C_{p+1}W_s)) ds.$$ 

where $W$ is a $d$-dimensional Brownian motion independent of $S_p$.

**Lemma B.2.** For every $\phi \in C^{2N+2}(\mathbb{R}^d)$ one has

$$E(\phi(S_p)) = E(h_{N,\sigma_{p+1}}^0 \phi(S_{p+1})) + E(h_{N,\sigma_{p+1}}^1 \phi(S_p)) \quad (B.3)$$

**Proof.** We notice that $G_{p+1}$ has the same law as $C_{p+1}W_1$, and moreover, we denote $\psi_\omega(x) = \phi(S_p(\omega) + x)$. Then, using the independence property and (B.1) we obtain

$$E(\psi_\omega(0)) = E(\psi_\omega(C_{p+1}W_1)) + \sum_{l=1}^N \frac{(-1)^l}{2^l l!} E(L_l^\sigma \psi_\omega(C_{p+1}W_1)) + \frac{(-1)^{N+1}}{2^{N+1} N!} \int_0^1 s^N E(L_{\sigma_{p+1}}^{N+1} \psi_\omega(C_{p+1}W_s)) ds.$$ 

Since $E(L_l^\sigma \psi_\omega(C_{p+1}W_1)) = E(L_l^\sigma \phi(S_{p+1}))$ and $E(L_{\sigma_{p+1}}^{N+1} \psi_\omega(C_{p+1}W_s)) = E(L_{\sigma_{p+1}}^{N+1} \phi(S_p+C_{p+1}W_s))$ the above formula is exactly (B.3). $\square$
