Abstract

The paper deals with the nonlinear stochastic dynamics concerning the detuning optimization in presence of random mistuning of bladed-disks with geometrical nonlinearities. We present an efficient computational methodology for reducing the computational cost, an analysis of the detuning, and the detuning optimization, based on the use of a high-fidelity computational model. A deep computational analysis is presented for a 12-bladed-disk structure that is representative of industrial turbomachines in order to understand the role played by the geometrical nonlinearities on the dynamical behavior and to exhibit the consequences on the detuning effects. For the detuning optimization with a very large number of possible detuned configurations, we propose a reformulation of the combinatorial optimization problem in a probabilistic framework, which is adapted to a probabilistic machine learning tool in order to limit the number of evaluations of the cost function with the high-fidelity computational model. The methodology proposed is validated for the 12-bladed-disk structure for which the exact optimal detuned configuration has been identified. A very good prediction is obtained.

Key words: nonlinear stochastic dynamics, bladed-disk, detuning, mistuning, reduced-order model, uncertainty quantification, combinatorial optimization, machine learning, probabilistic learning, PLoM

1. Introduction

The vibrational behavior of turbomachines is known to be particularly complex, requiring the construction of predictive computational models that have also to be efficient in terms of numerical costs. One of the issues concerns the mistuning caused by the small variations of the mechanical properties from one sector to another one, induced by the manufacturing tolerances or by the wear and tear of the structure. Such phenomenon can generate strong localization effects yielding larger dynamical amplifications of the forced response with respect to the perfect cyclic symmetry case [1, 2, 3]. This amplification strongly affects the fatigue life of the blades,
which can cause safety problems and impair the proper operation of turbomachines. Many research have been carried out on this subject, requiring the use of probabilistic approaches for modeling the random character of the mistuning combined to the construction of reduced-order models [4, 5, 6, 7, 8, 9, 10, 11] when linear assumption is considered. There also exist other phenomena that can strongly affect the vibrational behavior of the bladed-disk and that have to be the subject of a dedicated modeling. The presence of nonlinearities increases the complexity of the forced response analysis because couplings and energy transfers can strongly modify the position and the nature of the resonances of the bladed-disk. Contact nonlinearities occur for fan-type bladed-disks for which the disk and the blades are manufactured independently and for which the blade assembly is mounted on the disk with “fir-tree” or dovetail fixings. Such local nonlinearities although occur through rotor/stator interaction between the blade tip and the stator casing or when using under-platform dampers yielding blade to blade contact (see e.g. [12, 13, 14, 15, 16, 17, 18]). A research effort has also been made for the construction of nonlinear reduced-order models allowing for the mistuning analysis of bladed-disk in presence of contact nonlinearities [19, 20, 21, 22, 23, 24, 25]. Moreover, due to technological evolutions that involve lighter materials and thinner blades, the nonlinear geometrical effects induced by finite displacements cannot longer be neglected. The main difficulties concerning the modeling of these nonlinear geometrical effects concern the construction of adapted nonlinear reduced-order models that have to be efficient not only in terms of computational costs but also in terms of predictability. These aspects have also been investigated in the more general context of thin and slender structures [26, 27, 28, 29, 30, 31]. Concerning the context of turbomachines, various research can be found for the deterministic case [32, 33, 34], but also in presence of contact nonlinearities [35] or in presence of mistuning [36].

The intentional mistuning, also called detuning, consists in voluntarily breaking the cyclic symmetry of the structure by using partial or alternating patterns of different sector types. The detuning allows for spreading the frequencies of adjacent blades and thus for reducing the interaction between them. As a consequence, the drastic amplification and localization effects caused by the random mistuning can be greatly reduced. Such technology is particularly relevant because it is a way for reducing the response amplification levels that are induced by the unavoidable random mistuning while increasing its robustness. It has been thoroughly studied in the framework of linear dynamics [37, 38, 39, 40, 41, 42, 43, 44, 45, 46].

In a context of sustainable development, technological innovations have to be compatible with energy and environmental issues. This gives rise to the development and to the use of lighter materials, that have to be capable of high thermo-mechanical resistance and of long durability, so that it may be possible that the blade displacements respond in its nonlinear vibration range. In this context, a computational methodology and a robust analysis of the geometrical nonlinear effects on several detuned configurations of mistuned bladed-disk have been proposed in [47]. The results underline a complex nonlinear dynamical behavior and highlight a sensitivity of the nonlinear response to the detuning in presence of mistuning. Nevertheless, a too few number of detuned configurations is available and is not sufficient to perform a full optimization analysis with respect to the set of all possible detuned configurations of mistuned structures. This latter one has a huge dimension that increases exponentially with respect to the number of blades.

Novelties of the paper. The first novelty is the development of an efficient computational methodology in nonlinear stochastic dynamics for reducing the computational cost using a high-fidelity computational model (HFCM), and a deep computational analysis of a 12-bladed-disk structure that is representative of industrial turbomachines in order (i) to understand the role played by the
geometrical nonlinearities on the dynamical behavior and (ii) to construct the solution of the detuning optimization problem and to analyze the optimization results. For the case for which the set of all the possible detuned configurations cannot be computed with the HFCM, we propose a novel probabilistic approach consisting in estimating a small subset (a few units) of detuned configurations that improve the dynamical responses with respect to the configuration without detuning in presence of random mistuning. This approach is based on a probabilistic formulation of the combinatorial optimization problem and on the use of a probabilistic learning tool for estimating the cost function without using the HFCM.

**Organization of the paper.** Section 2 is devoted to the formulation, the methodology, the computational model, and the algorithms for the nonlinear stochastic dynamics analysis of rotating detuned bladed-disks with geometrical nonlinearity in presence of random mistuning. The chosen formulation is compatible with the use of the nonparametric probabilistic approach of uncertainties for modeling the random character of the mistuning. We describe in details the specific numerical difficulties encountered (i) in the computation of the nonlinear internal forces and its related tangent stiffness matrix, and (ii) in the use of the nonlinear solver. In Section 3, we present a full analysis of a representative computational model of the 12-bladed-disk structure and the analysis of the detuned configurations. All the numerical parameters involved in the computational process are carefully optimized in order to be able to generate a full data basis for constructing the exact solution of the detuning optimization problem. In Section 4, for the general case for which the number of detuned configurations is very large, we present a probabilistic formulation of the combinatorial optimization problem and a probabilistic learning tool for constructing a surrogate model of the cost function. This formulation is able to capture the amplification level of a detuned configuration of the mistuned structure with respect to the configuration without detuning in presence of random mistuning (pure mistuned configuration). The statistics post-processing of the computational results yields a small subset of optimized configurations whose characteristics are analyzed in details. The proposed approach is validated using the computational analysis performed in Section 3 for the 12-bladed-disk structure.

**Notations**

Lower-case letters such as $q$ or $\eta$ are deterministic real variables.

Boldface lower-case letters such as $\mathbf{q}$ or $\mathbf{\eta}$ are deterministic vectors.

Upper-case letters such as $X$ or $H$ are real-valued random variables.

Boldface upper-case letters such as $\mathbf{X}$ or $\mathbf{H}$ are vector-valued random variables.

Lower-case letters between brackets such as $[x]$ or $[\eta]$ are deterministic matrices.

Boldface upper-case letters between brackets such as $[\mathbf{X}]$ or $[\mathbf{H}]$ are matrix-valued random variables.

$\delta_K$: hyperparameter controlling the mistuning rate.

$\delta x$: displacement field $x \mapsto \delta x(x)$.

$\delta_{\text{opt}}$: Kronecker’s symbol.

$f_{\text{HFCM}}$: mapping on $\mathcal{N}_c$ defined by HFCM.

$i$: imaginary unit such that $i^2 = -1$.

$n$: number of dof in the computational model.

$\text{nb}_1$: number of blades of type 1.

$\text{nb}_2$: number of blades of type 2.
\( n_c \): number of all the possible configurations.
\( n_{\text{sim}} \): number of Monte Carlo realizations.
\( n_w \): number of blades.
\( q_c \): amplification dynamic factor (QoI).
\( q_c^f \): QoI computed with HFCM from \( w_c^f \).
\( q_{\text{opt}} \): learned realization of \( Q \).
\( u \): vector of the \( M \) generalized coordinates.
\( w_c^j \): component \( j \) of \( w_c \) for blade number \( j \).
\( w_c \): vector in \( \mathbb{N}^c \) defining a configuration.
\( w_c^f \): \( \mathbb{N}_c \)-valued vector of \( C_c \) (given configuration).
\( w_c^f \): learned realization of \( W \).
\( \mathcal{F}_c \): cost function derived from \( J_c \).
\( J_{\text{opt}} \): optimal solution.
\( \mathcal{F}_{\text{opt}} \): unachievable optimal solution.
\( x = (x_1, x_2, x_3) \): point in \( \mathbb{R}^3 \).
\( u(t) \): displacement field at time \( t \).
\( X_M: \) discrete set of all the \( n_c = 216 \) configurations.
\( X_{ad} \): admissible set of displacement fields.
\( \mathbb{C} \): set of all the complex numbers.
\( C \): Hermitian vector space on \( \mathbb{C} \) of dimension \( n \).
\( D_d \): training set made up of \( N_d \) points \((q_c^f, w_c^f)\).
\( D_{\text{opt}} \): learned set made up of \( N_{\text{opt}} \) points \((q_{\text{opt}}, w_{\text{opt}})\).
\( E: \) mathematical expectation.
\( \mathbb{R}^+ \): set of positive symmetric \((n \times n)\) real matrices.
\( \mathbb{R}^{+*} \): set positive-definite symmetric \((n \times n)\) matrices.
\( N_c \): order of the blisk equal to \( n_w \).
\( N_{\text{opt}} \): number of points in the learned set.
\( N_{\text{d}} \): number of points in the training set.
\( N_{\text{c}} \): discrete set \( \{0, 1\}^n \).
\( \mathbb{N} \): set of all the integers.
\( Q \): random QoI constructed with PLoM.
\( Q^f \): random QoI such that \( Q_c = f_{\text{HFCM}}(W) \).
\( Q: \) dimension of matrix \([G(\delta K)]\).
\( \mathbb{R} \): set of all the real numbers.
\( \mathbb{R}^n \): Euclidean vector space on \( \mathbb{R} \) of dimension \( n \).
\( U(t) \): \( u(t) \) in the finite element approximation.
\( U^f(t) \): \( U(t) \) for detuned configuration \( \ell \).
\( W \): \( \mathbb{R}^n \)-valued random variable associated with \( W_c \).
\( W^k \): component \( k \) of \( W \).
2. Stochastic computational model for dynamic analysis of rotating bladed-disk with geometrical nonlinearities: formulation, methodology, and algorithms

2.1. Assumptions

In the present work, the detuned bladed-disk structure has $N$ blades and is assumed (1) to be made up of a linear elastic material, (2) to be submitted to external forces whose amplitude is sufficiently large so that the structure undergoes geometrical nonlinear effects induced by large displacement, (3) to rotate at a constant velocity $\Omega$ around the rotation axis defined by $(0, Z)$, (4) to be constituted of different types of blades whose spatial distribution characterizes a detuned configuration. In this work, two different sector types are considered. These two types have an identical geometry but the blades have different material properties.

We have then to distinguish the tuned configuration from the detuned configurations. The tuned structure is related to the conceptual structure that has a perfect $N$-order cyclic symmetry. In consequence, the geometrical domain, the constitutive equations and the boundary conditions related to the generating sector are invariant under the $2\pi/N$ rotation around the symmetry axis $(0, Z)$. A detuned configuration corresponds to a modification of the tuned structure for which there is a spatial distribution of different types of sectors. For instance, if $N = 12$ and if there are two different types of sectors $A$ or $B$, a pattern denoted by $3A4B3A2B$ is constituted of 3 consecutive blades with type $A$, 4 with type $B$, 3 with type $A$ and 2 with type $B$. The tuned configuration can also be viewed as a particular detuning case. It should be also noted that detuned configurations can also be sub-cyclic which means that they present a cyclic symmetry with order $\bar{n} < N$, where $\bar{n}$ is a divisor of $N$. All these detuned configurations are characterized by the superscript $\ell$. 

\textbf{W}: random variable with values in $N_c$.
\textbf{W}^{opt}$: subset of optimal solutions.
$X(t)$: finite element discretization of $x(t)$.
$X^\ell(t)$: $X(t)$ for detuned configuration $\ell$.
$[x]_{ij}$: entry of matrix $[x]$.
$\langle x, y \rangle$: Euclidean or Hermitian inner product.
$\|x\|$: Euclidean or Hermitian norm $\langle x, x \rangle^{1/2}$.
blisk: turbomachine component comprising both rotor disk and blades.
dof: degree of freedom.
pdf: probability density function.
ANN: artificial neural network.
FFT: Fast Fourier Transform.
HFCM: high-fidelity computational model.
KDE: kernel density estimation.
MCMC: Markov chain Monte Carlo.
NL-ROM: nonlinear reduced-order model.
NL-SROM: nonlinear stochastic reduced-order model.
PCA: principal component analysis.
PLoM: probabilistic learning on manifolds.
QoI: quantity of interest.
ROB: reduced-order diffusion-maps basis.
The real systems that are related to these detuned structures are modeled by introducing mistuning (unintentional mistuning) that is modeled by using the nonparametric probabilistic approach of uncertainties [48, 49]. We then can distinguish the pure mistuning situation, from which the conceptual system is modeled with the tuned structure from the detuned structures that are considered in presence of mistuning.

2.2. Description of the geometric nonlinear boundary value problem of a detuned configuration

The superscript \( \ell \) is omitted in this Section. Let \( \Omega \) be the three-dimensional bounded domain of the physical space \( \mathbb{R}^3 \) corresponding to the steady configuration of a detuned structure observed in the rotating frame that is defined as the reference configuration of the boundary value problem [50]. The boundary \( \partial \Omega \) is such that \( \partial \Omega = \Gamma_0 \cup \Gamma_E \) with \( \Gamma_0 \cap \Gamma_E = \emptyset \) and the external unit normal to boundary \( \partial \Omega \) is denoted by \( n = (n_1, n_2, n_3) \) (see Fig. 1). The boundary part \( \Gamma_0 \) corresponds to the fixed part (in the rotating frame) of the structure whereas the boundary part \( \Gamma_E \) is submitted to an external surface force field. A total Lagrangian formulation is chosen. Consequently, the mechanical equations are written with respect to the reference configuration in the rotating frame. Let \( x = (x_1, x_2, x_3) \) be the position of a point belonging to domain \( \Omega \). The displacement field expressed with respect to the reference configuration is denoted as \( x(x, t) = (x_1(x, t), x_2(x, t), x_3(x, t)) \). It should be noted that the surface force field \( G(x, t) = (G_1(x, t), G_2(x, t), G_3(x, t)) \) acting on boundary \( \Gamma_E \) and the body force field \( g(x, t) = (g_1(x, t), g_2(x, t), g_3(x, t)) \) acting on domain \( \Omega \) correspond to the Lagrangian transport into the reference configuration of the physical surface force field and to the physical body force field applied on the deformed configuration. The nonlinear boundary value problem is written,

\[
\rho \frac{\partial^2 x_i}{\partial t^2} + 2\rho r_{ik} \frac{\partial x_k}{\partial t} + \rho r_{ik} r_{\ell k}(x_\ell + x_\ell) = \frac{\partial (F_{ij} S_{jk})}{\partial x_k} + g_i(t) \quad \text{in} \quad \Omega, \\
x_i = 0 \quad \text{on} \quad \Gamma_0, \\
F_{ij} S_{jk} n_k = G_i(t) \quad \text{on} \quad \Gamma_E, 
\]

for \( i = 1, 2, 3 \) and using the classical convention for summations over repeated indices, as

\[
[F r(\Omega)]_{ij} = r_{ij} = -\Omega \varepsilon_{ij3}, \quad \text{for the sake of clarity},
\]

in which \( \rho > 0 \) is the mass density expressed in the reference configuration, where the \( (3 \times 3) \) matrix \([F r(\Omega)]\) whose component \([F r(\Omega)]_{ij}\) is denoted as \( r_{ij} \) for the sake of clarity, is such that

\[
[F r(\Omega)]_{ij} = r_{ij} = -\Omega \varepsilon_{ij3},
\]

\[
6
\]
where \( \varepsilon_{ijk} \) is the Levi-Civita symbol such that \( \varepsilon_{ijk} = \pm 1 \) for an even or odd permutation and \( \varepsilon_{ijk} = 0 \) otherwise. In Eq. (17), \( [F_{ij}]_{ij} \) is the deformation gradient tensor whose components \( F_{ij} \) are defined by

\[
F_{ij} = x_{i,j} + \delta_{ij},
\]

(5)
in which \( \delta_{ij} \) is the Kronecker symbol such that \( \delta_{ij} = 1 \) if \( i = j \) and \( \delta_{ij} = 0 \) otherwise. In Eq. (5), \( x_{i,j} \) denotes the partial derivative \( \partial x_i / \partial x_j \). For a linear elastic material, the second Piola-Kirchoff symmetric stress tensor \( [S_{ij}]_{ij} \) is written as

\[
S_{ij} = \sigma^{(x)}_{ij} + a_{ijkl} E_{kl},
\]

(6)
in which \( [\sigma^{(x)}_{ij}]_{ij} \) is the symmetric Cauchy stress tensor acting on the reference configuration observed in the rotating frame. In Eq. (6), the fourth-order elasticity tensor \( [a_{ijkl}]_{ijkl} \) satisfies the usual symmetry and positive-definiteness properties. The Green strain tensor \( [E_{ij}]_{ij} \) is written as the sum of linear and nonlinear terms such that

\[
E_{ij} = \epsilon_{ij} + \eta_{ij},
\]

(7)
in which \( \epsilon_{ij} = (x_{i,j} + x_{j,i})/2 \) and where \( \eta_{ij} = x_{i,j} x_{j,i}/2 \). In the following, when no confusion is possible, symbol \( t \) denoting time is removed from the equations. Note that the first and the second partial derivatives of the displacement field with respect to \( t \) are denoted by \( \dot{x} \) and \( \ddot{x} \). In the rotating frame, we define the admissible space \( C_{ad} \) of the displacements as the set of all the sufficiently differentiable functions \( x \mapsto \delta x(x) \) from \( \Omega \) in \( \mathbb{R}^3 \) such that \( \delta x = 0 \) on \( \Gamma_0 \) (in the rotating frame). For all fixed \( t \), the weak formulation of the geometric nonlinear boundary value problem consists in finding the unknown displacement field \( x(t) \) in \( C_{ad} \) such that, for all \( \delta x \) in \( C_{ad} \),

\[
m(\dot{x}, \delta x) + (c(\dot{x}, \delta x) + d(\dot{x}, \delta x)) + k^{(1)}(x, \delta x) + k^{(2)}(x, x, \delta x) + k^{(3)}(x, x, x, \delta x) = f(\delta x),
\]

(8)
in which

\[
f(\delta x) = \int_{\Omega} \delta x_i g_i \, dx + \int_{\Gamma_k} \delta x_i G_i \, ds,
\]

(9)
with \( ds \) the surface element and where

\[
m(x, \delta x) = \int_{\Omega} \rho x_i \delta x_i \, dx, \quad m(x, x) > 0,
\]

(10)
\[
c(x, \delta x) = \int_{\Omega} 2 \rho r_{ij} \delta x_i \, dx, \quad c(x, x) = 0.
\]

(11)
The bilinear form \( k^{(1)} \) is written as

\[
k^{(1)}(x, \delta x) = k^{(e)}(x, \delta x) + k^{(v)}(x, \delta x) + k^{(o)}(x, \delta x),
\]

in which the positive-definite bilinear form \( k^{(e)} \), the negative-definite bilinear form \( k^{(v)} \), and the bilinear form \( k^{(o)} \) are written as

\[
k^{(e)}(x, \delta x) = \int \alpha_{ijkl} \epsilon_{lm}(x) \epsilon_{jk}(\delta x) \, dx,
\]

(12)
The computational model is constructed by discretizing Eq. (8) by the finite element method and is referred to as the high-fidelity computational model (HFCM). Such a nonlinear computational model is not explicitly constructed because of the large number of degrees of freedom occurring in industrial finite element models. This Section is devoted to the construction of the nonlinear reduced-order model (NL-ROM) of a detuned configuration without mistuning of the rotating structure. The superscript \( \ell \) characterizing the detuned configuration is omitted for clarity.

Let \( \{ \varphi^1, \ldots, \varphi^M \} \) be a given finite family of algebraically independent vectors in \( C_{ad} \). We introduce the notation \( A_{\alpha \beta} = a(\varphi^\alpha, \varphi^\beta) \) in which \( a(\varphi, \hat{\varphi}) \) is one of the bilinear forms defined by Eqs. (10) to (14). Similarly, we introduce the notations \( K_{\alpha \beta \gamma \delta}^{(2)} = k^{(2)}(\varphi^\alpha, \varphi^\beta, \varphi^\gamma, \varphi^\delta), K_{\alpha \beta \gamma \delta}^{(3)} = k^{(3)}(\varphi^\alpha, \varphi^\beta, \varphi^\gamma, \varphi^\delta) \), and \( F_{\alpha} = f(\varphi^\alpha) \). We define the vector \( \mathbf{u} = (u_1, \ldots, u_M) \) as
of the generalized coordinates as a new set of unknowns obtained by projecting the reference nonlinear response \( \eta(x, t) \) on the vector space spanned by the finite family \( \{ \phi_1, \ldots, \phi_M \} \),

\[
\eta(x, t) = \sum_{\beta=1}^{M} \phi_\beta(x) u_\beta(t).
\]

Let \( \delta(x) = \phi'(x) \) be a test function in \( C_{ad} \). Substituting \( \eta(x, t) \) and \( \delta(x) \) into Eq. (8), and using Eqs. (9) to (20) yields the following set of \( M \) nonlinear coupled differential equations such that, for \( \alpha \in [1, \ldots, M] \),

\[
M_{\alpha\beta} \ddot{u}_\beta + (C_{\alpha\beta} + D_{\alpha\beta}) \dot{u}_\beta + (K_{\alpha\beta}^{(c)} + K_{\alpha\beta}^{(s)} + K_{\alpha\beta}^{(q)}) u_\beta + F_{R_{\alpha}}(u) = F_{\alpha},
\]

in which \( F_{R_{\alpha}}(u) = (F_{R_1}(u), \ldots, F_{R_M}(u)) \) is the \( \mathbb{R}^M \)-vector of the reduced nonlinear internal forces whose component \( \alpha \) is written as

\[
F_{R_{\alpha}}(u) = K_{\alpha\beta\gamma}^{(2)} u_\beta \dot{u}_\gamma + K_{\alpha\beta\gamma}^{(3)} \ddot{u}_\beta \dot{u}_\gamma u_\delta,
\]

in which

\[
K_{\alpha\beta\gamma}^{(2)} = \frac{1}{2}(K_{\alpha\beta\gamma}^{(c)} + K_{\alpha\beta\gamma}^{(s)} + K_{\alpha\beta\gamma}^{(q)}),
\]

and where \( F = (F_1, \ldots, F_M) \) is the \( \mathbb{R}^M \)-vector of the reduced external forces whose component \( \alpha \) is \( F_\alpha = f(\phi^\alpha) \). The computational procedure concerning the computation of \( F_{R_{\alpha}}(u) \) requires to use the finite element method in order (1) to construct the quadratic stiffness contribution \( K_{\alpha\beta\gamma}^{(2)} \), to retrieve the quadratic stiffness contribution \( K_{\alpha\beta\gamma}^{(3)} \), according to Eq.(24), to construct the cubic stiffness contribution \( K_{\alpha\beta\gamma}^{(3)} \), and to compute the vector of the nonlinear reduced internal forces \( F_{R_{\alpha}}(u) \). The choice of such computational procedure is required by the choice of modeling the mistuning phenomenon through the nonparametric probabilistic approach [51]. All the details concerning the computation of the nonlinear internal reduced force vector can be found in [52].

The projection basis can be constructed as the linear elastic modes of the rotating structure associated with its first eigenfrequencies ordered in ascending order. It should be noted that in the case of a rotating structure, the generalized eigenvalue problem allowing such a computation is a nonsymmetric eigenvalue problem yielding a complex projection basis, due to the presence of the gyroscopic coupling term. Another projection basis can be chosen as the family of linear elastic modes constructed without considering the gyroscopic coupling term. With such a choice, the speed of convergence with respect to \( M \) of the projection remains fast enough for bladed-disks whose blades have a reasonable slenderness. When the gyroscopic coupling term is kept, an alternative method avoiding the calculation of complex modes can be used as proposed in [47]. It consists in using the proper orthogonal decomposition method (POD) applied to the nonlinear dynamical response of the rotating structure (including all the coupling terms) issued from a first nonlinear reduced-order model obtained with the linear elastic modes calculated without the gyroscopic coupling term.

Let \( n \) be the number of dofs of the HFCM. Let \( [\Phi] \) be the \( (n \times M) \) matrix whose columns are the vector of the projection basis (in the finite element discretization). At time \( t \), the physical response of the detuned bladed-disk, constructed using the HFCM, is written as

\[
\chi(t) = [\Phi] \mathbf{U}(t),
\]

in which \( \chi(t) \) is the \( \mathbb{R}^n \)-vector of the physical displacements and \( \mathbf{U}(t) \) is the \( \mathbb{R}^M \) vectors of the generalized coordinates \( U_1(t), \ldots, U_M(t) \).
2.4. Construction of the NL-SROM related to a detuned configuration in presence of mistuning

In this paragraph, we are interested in constructing the nonlinear stochastic reduced-order model (NL-SROM) related to a detuned configuration of the bladed-disk in presence of random mistuning. It is assumed that the mistuning only affects the linear elastic internal force and the nonlinear forces, which are therefore uncertain. Such mistuning is modeled through the nonparametric probabilistic approach [49] for geometric nonlinearities [51], which is briefly summarized below. A global stiffness ($P \times P$) real symmetric matrix $[K^{\text{NL}}]$, with $P = M(M + 1)$, containing all the linear, quadratic, and cubic elastic stiffness contributions, is constructed such that

$$[K^{\text{NL}}] = \begin{bmatrix} [K^{(0)}] & [K^{(2)}] \\ [K^{(2)}]^T & 2[K^{(3)}] \end{bmatrix},$$

(26)

in which $[K^{(0)}]$ is the $(M \times M)$ matrix defined by $[K^{(0)}]_{\alpha \beta} = K_{\alpha \beta}^{(0)}$ and where the block matrices $[K^{(2)}]$ and $[K^{(3)}]$ are the $(M \times M^2)$ and the $(M^2 \times M^2)$ real matrices resulting from the following reshaping operation,

$$[K^{(2)}]_{\alpha \beta \gamma} = K_{\alpha \beta \gamma}^{(2)} \quad J = (\beta - 1)M + \gamma,$n

(27)

$$[K^{(3)}]_{\alpha \beta \gamma \delta} = K_{\alpha \beta \gamma \delta}^{(3)} \quad I = (\alpha - 1)M + \beta, \quad J = (\gamma - 1)M + \delta.$$

(28)

In [51], it is proven that $[K^{\text{NL}}]$ is a positive-definite matrix that is modeled by a random matrix $[K^{\text{NL}}]$. In this work, we use the nonparametric probabilistic modeling proposed in [53] for random matrix $[K^{\text{NL}}]$.

(29)

The matrix $[L_K]$ is a full $(Q \times P)$ matrix for which $Q \ll P$, defined by $[L_K] = [LQ]^T$. The columns of $[LQ]$ are the $Q$ eigenvectors of matrix $[K^{\text{NL}}]$ related to its first $Q$ largest eigenvalues that are stored in the diagonal matrix $[LQ]$. The full $(Q \times Q)$ random matrix $[G(\delta_K)]$ is then constructed according to the nonparametric probabilistic approach [54, 49] for which the uncertainty level is controlled by a scalar hyperparameter $\delta_K$. The random matrix $[K^{\text{NL}}]$ is block-decomposed similarly to Eq. (26), which allows for extracting the random stiffness terms $K_{\alpha \beta \gamma}^{(2)}$, $K_{\alpha \beta \gamma}^{(3)}$, and $K_{\alpha \beta \gamma}^{(4)}$. The random quadratic term $K_{\alpha \beta \gamma}^{(2)}$ is then reconstructed according to Eq. (18) by using the formula

$$K_{\alpha \beta \gamma}^{(2)} = \frac{1}{2} (K_{\alpha \beta \gamma}^{(2)} + K_{\alpha \gamma \beta}^{(2)} + K_{\gamma \alpha \beta}^{(2)}).$$

(30)

The NL-SROM of a detuned configuration $\ell$ of the rotating bladed-disk in presence of mistuning is then written (see Eq. (25)) as

$$x^e(t) = [\Phi^e] U^e(t),$$

(31)

in which $x^e(t)$ is the $\mathbb{R}^n$-valued random vector corresponding to the nonlinear random displacements at time $t$ of the HFCM for the detuned configuration $\ell$ in presence of mistuning. At time $t$, the $\mathbb{R}^n$-valued random vector $U^e(t)$ of the generalized coordinates is then solution of the random nonlinear coupled differential equations, which are written, for $\alpha \in \{1, \ldots, M\}$, as

$$M_{\alpha \beta} \ddot{U}_{\beta}^e + (G_{\alpha \beta} + D_{\alpha \beta}) U_{\beta}^e + (K_{\alpha \beta}^{(0)} + K_{\alpha \beta}^{(2)}) U_{\beta}^e + \mathcal{F}_\alpha^\text{NL,e}(U^e) = \mathcal{F}_\alpha^e,$$

(32)

in which the component $\alpha$ of the $\mathbb{R}^m$-valued random vector $\mathcal{F}_\alpha^\text{NL,e}(U^e)$ is

$$\mathcal{F}_\alpha^\text{NL,e}(U^e) = K_{\alpha \beta \gamma}^{(2)} U_{\beta}^e U_{\gamma}^e + K_{\alpha \beta \gamma}^{(3)} U_{\beta}^e U_{\gamma}^e U_{\delta}^e.$$
The observation (quantity of interest) that is adapted to the detuning context in presence of random mistuning and that allows to quantify the dynamical amplification of the detuned configuration with random mistuning with respect to the configuration without detuning in presence of random mistuning, is defined in Section 3 (see Eq. (38)).

2.5. Numerical aspects related to the algorithms

This section is devoted to the computational strategy used for solving the NL-SROM. In the detuning context, the number $n_c$ of distinct detuned configurations rapidly increases with the number $N$ of blades of the bladed-disk as $n_c \approx 2^{N/N}$. Furthermore, the NL-SROM is solved with the Monte-Carlo numerical simulation using $n_{\text{sim}}$ realizations for which the numerical convergence has to be achieved in order to perform statistics post-processing. This means that there is a large number $n_c \times n_{\text{sim}}$ of nonlinear differential equations with order $M$ to be solved. Note that, in general for industrial bladed-disks, $n_c$ is very large and it is impossible to solve $n_c \times n_{\text{sim}}$ times the nonlinear reduced-order computational model, even with an efficient algorithm. Only a small number $N_d \ll n_c$ of detuned configurations in presence of mistuning can be computed. This is the reason why a surrogate model will be constructed in Section 4 with a probabilistic learning tool in order to solve the probabilistic-based combinatorial optimization problem and which will allow an optimal detuned configuration to be identified. In consequence, the computational algorithms require to be efficient in terms of computational costs. A careful attention has been paid in order to be able to browse the set of all the possible detuned configurations in presence of mistuning using the HFCM, when $n_c$ is not to large. This approach is presented and analyzed in Section 3 and the obtained results will be used for validating the solving method of the probabilistic-based combinatorial optimization problem using a probabilistic learning tool, presented in Section 4.

2.5.1. Computational strategy for dealing with geometrical nonlinearities

In a deterministic finite element context, it should be noted that the construction of the linear reduced operators in Eq. (22) is usual and can easily be extracted using commercial softwares. From a computational point of view, the vector of the nonlinear reduced internal forces $F_{NL}(U)$ and the tangential matrix, for which the nonlinear stiffness contribution is written as

$$[K_{NL}^T(U)]_{\alpha\beta} \delta U_{\beta} = \frac{\partial F_{NL}(U)}{\partial U_{\beta}} \delta U_{\beta},$$

can also be extracted. Nevertheless, vector $F_{NL}(U)$ is usually constructed by directly computing the contribution related to each finite element, without distinguishing the quadratic stiffness entries from the cubic stiffness entries. In such a case, the assemblage is quickly performed as a simple summation. In general, tangential matrix $[K_{NL}^T(U)]$ is deduced from finite differences techniques. The present methodology requires the knowledge of entries $\hat{K}^{(2)}_{\alpha\beta\gamma}$ and $K^{(3)}_{\alpha\beta\gamma\delta}$. Its detailed construction can be found in [52]. In the detuning context in presence of random mistuning, the computational procedure allowing for computing the random quantities $F_{NL}(U)$ and $[K_{NL}^T(U)]$ issued from the NL-SROM is summarized hereinafter.

1. Commercial software extraction or direct construction of the reduced linear elastic stiffness $K_{\alpha\beta}^{(\varepsilon)} = k^{(\varepsilon)}(\psi^\alpha, \psi^\beta)$ according to Eq. (12).

2. Construction of the quadratic stiffness contribution $\hat{K}^{(2)}_{\alpha\beta\gamma} = k^{(2)}(\psi^\alpha, \psi^\beta, \psi^\gamma)$ and of the cubic stiffness contribution $K^{(3)}_{\alpha\beta\gamma\delta} = k^{(3)}(\psi^\alpha, \psi^\beta, \psi^\gamma, \psi^\delta)$ according to Eqs. (19) and (20).
3. Construction of the global stiffness matrix $[\mathcal{K}^{\text{NL}}]$ according to Eq. (26),
4. Construction of the random global stiffness matrix $[\mathcal{K}^{\text{NLr}}]$ according to Eq. (29), by optimizing the size $Q$ of random matrix $[\mathcal{G}(\delta_k)]$;
5. Extraction from random matrix $[\mathcal{K}^{\text{NLr}}]$ of random quantities $\mathcal{K}^{(\alpha)}_{\alpha \beta \gamma \delta}$, $\mathcal{K}^{(2)}_{\alpha \beta \gamma \delta}$, and $\mathcal{K}^{(3)}_{\alpha \beta \gamma \delta}$ and retrieving random stiffness $\mathcal{K}^{(2)}_{\alpha \beta \gamma \delta}$ according to Eq. (30);
6. Computational evaluation of random nonlinear internal reduced force vector $\mathbf{\mathcal{F}}^{\text{NL}}(\mathbf{U})$ according to Eq. (33);
7. Depending on the computational algorithms used for solving nonlinear equations, computing the tangential matrix related to the nonlinear contribution $[\mathcal{K}^{\text{NL}}_T(\mathbf{U})]$ such that $[\mathcal{K}^{\text{NL}}_T(\mathbf{U})]_{\alpha \beta} = \mathcal{K}^{(2)}_{\alpha \beta \gamma \delta} U_{\gamma} + \mathcal{K}^{(2)}_{\alpha \gamma \delta \beta} U_{\delta} + \mathcal{K}^{(3)}_{\alpha \beta \gamma \delta} U_{\gamma} U_{\delta} + \mathcal{K}^{(3)}_{\alpha \gamma \delta \beta} U_{\gamma} U_{\delta} + \mathcal{K}^{(3)}_{\alpha \beta \delta \gamma} U_{\delta} U_{\gamma}.$

2.5.2. Computational strategy for the nonlinear solver

The problem investigated concerns the forced regime of the bladed-disk, that is to say the nonlinear forced response that does not depend on initial conditions. The external excitation is thus a square integrable real-valued function on $\mathbb{R}$ whose Fourier transform has a compact support (see Section 3.3). For a given detuned configuration $\ell$ with random mistuning, the NL-SROM is solved in the time domain. An implicit unconditionally stable integration scheme corresponding to the Newmark method with an averaging acceleration scheme is chosen. With such integration scheme, for a given sampling time $t_i$, we then have to solve the following set of nonlinear coupled equations such that, for $\alpha = 1, \ldots, M,$

$$\mathcal{K}^{\text{eff}}_{\alpha \beta} U_{\beta}(t_i) + \mathcal{F}^{\text{NL}}_{\alpha}(\mathbf{U}(t_i)) = \mathcal{F}^{\text{eff}}_{\alpha}(t_i).$$ \hspace{1cm} (34)

In Eq. (34), the random matrix $[\mathcal{K}^{\text{eff}}]$ is the reduced effective stiffness matrix that is independent from sampling time. Note that $[\mathcal{K}^{\text{eff}}]$ is positive definite almost surely for a fixed structure and is without signature for a rotating structure due to the antisymmetric gyroscopic coupling term. The random vector $\mathcal{F}^{\text{eff}}(t_i)$ models the effective external load that has to be updated at each sampling time $t_i$.

There are several ways to solve iteratively such nonlinear coupled equation. The simplest method that is used is the fixed point method. The main advantage is that this iterative scheme is computationally expedient because it does not require the evaluation of the tangential matrix. Nevertheless, the algorithm does not necessarily converge. When the fixed-point algorithm does not converge, it can be replaced by a Newton-Raphson algorithm [55]. It should be noted that such algorithm requires the computation of the tangential matrix that is particularly time consuming. Furthermore, for nonlinear computations corresponding to a snap-back or snap-through behavior, the Newton algorithm does not converge beyond the critical limit corresponding to a null tangential stiffness matrix. In this case, the arc-length algorithm appears to be efficient for computing the solution. Nevertheless, such algorithm introduces a new additional scalar parameter $\xi(t_i)$ that multiplies the right-hand side member of the nonlinear equation. In this case, we then introduce the residual random vector $\mathbf{\mathcal{R}}(\mathbf{U}(t_i), \xi(t_i))$ whose component $\alpha$ is defined by

$$\mathcal{R}_{\alpha}(\mathbf{U}(t_i), \xi(t_i)) = \xi(t_i)\mathcal{F}^{\text{eff}}_{\alpha}(t_i) - [\mathcal{K}^{\text{eff}}_{\alpha \beta}] U_{\beta}(t_i) - \mathcal{F}^{\text{NL}}_{\alpha}(\mathbf{U}(t_i)).$$ \hspace{1cm} (35)

The algorithm is iterative. Several numerical approximations can be made. The first one consists in keeping the same tangential matrix $[\mathcal{K}^{\text{NL}}_T(\mathbf{U}(t_i))]$ along the successive iterations. The second one concerns the computation of the increment related to parameter $\xi(t_i).$ The pure spherical
The arc-length method is based on the fact that there always exists a hypersphere that intersects the load curve [56]. It then requires to solve a quadratic equation and to select amongst the two solutions the physical root. Improvements have been proposed based on linearization methods, for which the hypersphere is replaced by an hyperplan that is updated at each iteration [57] or not updated [58]. For a given sampling time $t_i$, such iterative scheme allows for computing a solution $(U(t_i), \zeta(t_i))$ but does not allow for controlling the value of $\zeta(t_i)$. In the present case, the process is incrementally repeated in order to increase the value of $\zeta(t_i)$ that has to be controlled to 1. In order to achieve that, an adaptive arc length, depending on the number of iterations necessary to obtain the convergence of the previous increment is also implemented according to [55]. An unusual procedure is then added to the algorithm concerning parameter $\zeta(t_i)$. The state of the algorithm corresponding to the previous increment is stored. As the new incremental value of $\zeta(t_i)$ is found to be upper than 1, the algorithm is rewind to the previous increment and the computation is set again with the half of the arc-length. Such additional procedure is repeated until parameter $\zeta(t_i)$ reaches 1 within a numerical tolerance set.

3. Computational analysis of the role played by the geometrical nonlinearities in the detuned bladed-disk in presence of random mistuning and detuning optimization

For the computational analysis, we have deliberately chosen a blisk (turbomachine component comprising both rotor disk and blades) with mistuning with a relatively small number of blades so that the number of all the possible detuned configurations be also small. This will allow us

1. to present a complete analysis of the role played by geometrical nonlinearities in the detuned blisk in presence of random mistuning,

2. to build an exact solution (as the reference) of the combinatorial optimization problem introduced in Section 4. This reference will allow for validating the formulation of the combinatorial optimization problem (see Sections 4.1 to 4.5) and for validating the probabilistic machine learning tool for constructing a metamodel of the cost function (see Section 4.6 to 4.8). If we had chosen a larger number of blades, we would not have been able to build the reference solution of the combinatorial optimization problem, reference that is required for validation.

3.1. Description of the finite element model

The structure under consideration is a blisk with order $N = 12$ and with $n_w = N = 12$ blades whose finite element computational model is constructed with hexahedral solid finite elements with 8 nodes. The finite element mesh is issued from [59] for which the order of the cyclic symmetry has been modified from 24 to 12 as also used in [41]. The main motivation of such reduction of the number of blades is to decrease the number of possible detuning patterns in order to have a reasonable number of detuning possibilities, as previously explained. In the present case, the aim is to constitute a full reference data basis in the nonlinear mistuned/detuned context. When the detuning concept is approached with 2 possible types of blades, there are 352 possible detuned configurations when $N = 12$ that reduces the number of possibilities by a factor of almost $2^{N-1} \approx 2000$ with respect to a structure with cyclic symmetry of order $2N = 24$. Let $(0, X, Y, Z)$ be the Cartesian reference coordinate system for which $(0, Z)$ coincides with the rotational axis for the blisk. Fig. 2 shows the finite element mesh of the blisk whose computational characteristics are summarized in Table 1. There are $n = 27108$ degrees of freedom (dof). The blisk is made up of a homogeneous and isotropic material with mass density $7860 \text{ Kg/m}^3$. 

13
Poisson ratio 0.25, and Young modulus $2 \times 10^{11} \text{N/m}^2$. A Dirichlet condition is applied along the interfaces toward adjacent stages \[59\]. The fundamental frequency of the blisk is $\nu_0 = 977.32 \text{ Hz}$. A Rayleigh damping model (see Eq. (17)) is added for the blisk, with parameters $\alpha = 78.67 \text{s}^{-1}$ and $\beta = 3.69 \times 10^{-7} \text{s}$ chosen such that the critical damping rate $\zeta(2\pi\nu)$ belongs to $[0.0054, 0.008]$ for $\nu \in [900, 6000] \text{Hz}$ as shown in Fig. 3.

3.2. Modal characteristics of the tuned blisk

The eigenfrequencies (natural frequencies) of the structure are computed using the cyclic symmetry. Fig. 4 displays the eigenfrequencies of the tuned blisk with respect to its circumferential wave number. The graph exhibits several veerings. Let $\nu_{h,i}$ be the eigenfrequency number $i$ related to the number $h$ of nodal diameters. In the present case, the veering corresponding to $h = 2$ nodal diameters corresponds to (double) eigenfrequency $\nu_{2,4} = 4.845.18 \text{ Hz}$ that is related to a dominant blade motion and to (double) eigenfrequency $\nu_{2,5} = 5.091.09 \text{ Hz}$ that is related to a blisk global motion as can be shown in Fig. 5.
Figure 3: Critical damping rate: graph of $\nu \mapsto \xi(2\pi\nu)$. Square symbol is related to fundamental frequency $\nu_0 = 977.32\, \text{Hz}$ and $\xi_0 = \xi(2\pi\nu_0) = 0.00754$.

Figure 4: Graph of the eigenfrequencies $\nu$ of the tuned blisk with respect to its circumferential wave number $h$.

3.3. Choice of the external excitation and time-frequency sampling

Since we are interested in the forced response of the structure, the presence of geometrical nonlinearities requires to solve the nonlinear equations in the time domain. The time-dependent external excitation is modeled by the $\mathbb{R}^n$-vector $F(t)$ whose block decomposition according to each sector is given by $F(t) = (F^0(t), \ldots, F^{N-1}(t))$ such that

$$F^j(t) = s_0 g^j(t) \bar{r}, \quad j \in \{0, 1, \ldots, N-1\},$$

in which $s_0$ is the load intensity that allows the nonlinearity rate to be calibrated, $t \mapsto g^j(t)$ is a square integrable real-valued function on $\bar{R}$, which characterizes the time evolution of the load, and where $\bar{r}$ is a $\mathbb{R}^n$-vector describing the space localization of the load related to a given sector.
in which integer $\overline{n}$ is equal to $n/N$. The Fourier transform of function $t \mapsto g^j(t)$ is the $\mathbb{C}$-valued function again noted $g^j$, but for which its argument is $2\pi \nu$, such that

$$g^j(2\pi \nu) = \int_{\mathbb{R}} e^{-2\pi i \nu t} g^j(t) \, dt, \quad \nu \in \mathbb{R},$$
in which $t$ is the imaginary unit. Complex-valued function $\nu \mapsto g'(2\pi \nu)$ is assumed to have a compact support $\mathbb{B}_c \cup \mathbb{E}_c \in \mathbb{R}$, independent of $j$, with $\mathbb{E}_c = [-\nu_{\min}, -\nu_{\max}]$ and $\mathbb{B}_c = [\nu_{\min}, \nu_{\max}]$.

This support is chosen as the frequency band of excitation for which $\nu_{\min} = 4 \, 700 \, \text{Hz}$ and $\nu_{\max} = 5 \, 200 \, \text{Hz}$ (see Fig. 7) in order that $\mathbb{E}_c$ contains the veering region for $h = 2$ (see Fig. 4). Time function $g'$ differs from one sector to another by a constant phase shift $\varphi_j = (4\pi j)/N$. This choice of the phase allows the modes with $h = 2$ nodal diameters to be excited for the linearized dynamical system. For all $t$ in $\mathbb{R}$, we write

$$g'(t) = \sum_{k=1}^{S} \frac{2}{\pi t} \sin(\pi \Delta \nu t) \cos(2\pi s_k \Delta \nu t + \varphi_j)$$

in which $\Delta \nu = (\nu_{\max} - \nu_{\min})/S$ and where $s_k = \nu_{\min}/\Delta \nu + (2k - 1)/2$. Consequently, $|g'(2\pi \nu)| = 1$ if $\nu$ belongs to $\mathbb{E}_c \cup \mathbb{B}_c \in \mathbb{R}$ and is equal to 0 if does not. Therefore, the structure is uniformly excited in band $\mathbb{E}_c$. From a numerical point of view, the computation is carried out on a truncated time domain $\mathbb{T} = [t_{\min}, t_{\min} + T]$. The initial time is chosen as $t_{\min} = -0.06 \, s$ yielding a null initial load. The time duration $T$ is then adjusted so that the system be returned at its equilibrium state with a negligible relative tolerance.

The efficiency and the accuracy of the Newmark time integration scheme coupled with a Newton-Raphson procedure is investigated. The load intensity is set to $s_0 = 10 \, N$ that corresponds to a situation for which nonlinear effects occur, involving displacements of magnitude $2 \times 10^{-3} \, m$ at the tip of blade, knowing that the blade thickness is $6.7 \times 10^{-3} \, m$. The nonlinear reduced-order model is then constructed with $M = 72$ elastic modes corresponding to increasing eigenfrequencies up to $\nu_{6,12} = 10 \, 835.13 \, \text{Hz}$. The frequency band of analysis $\mathbb{B}$ is chosen as $\mathbb{B} = [300, 6 \, 000] \, \text{Hz}$. We are then interested in the nonlinear computations for which the nonlinear response is calculated in the truncated time domain $\mathbb{T} = [-0.06, 0.06] \, s$. For performing the convergence analysis, the values of parameters $\delta t$, $n_s$, and $\nu_e$ are given in Table 2.
Let $\mathbf{u} = (u_1, \ldots, u_M)$ be the vector of the $M$ modal coordinates. Let $\delta t \mapsto \text{Conv}_2(\delta t)$ be the convergence function defined by

$$\text{Conv}_2(\delta t) = \sqrt{\int_{\mathbb{B}} ||\mathbf{u}(2\pi \nu; \delta t)||^2 d\nu},$$

in which $||\mathbf{u}(2\pi \nu; \delta t)||^2 = \sum_{i=1}^{M} |u_i(2\pi \nu; \delta t)|^2$ and where the $\mathbb{C}^M$-vector $\mathbf{u}(2\pi \nu; \delta t)$ is the Fourier

The transform of the $\mathbb{R}^M$-valued function $t \mapsto u(t; \delta t)$. Fig. 8 shows the graph of $\delta t \mapsto \text{Conv}_3(\delta t)$. It can be seen that a reasonable convergence is obtained for $\delta t = 15.6 \times 10^{-6} \text{s}$ yielding $n_t = 8192$ time steps, $\nu_c = 64000 \text{ Hz}$, and a frequency resolution $\delta \nu = 7.8 \text{ Hz}$.

![Figure 8: Convergence analysis with respect to time sampling $\delta t$. Graph of function $\delta t \mapsto \text{Conv}_3(\delta t)$.](image)

Let $x_{\text{tip}}(t) = (x_{\text{tip}}^1(t), x_{\text{tip}}^2(t), x_{\text{tip}}^3(t))$ be the displacement vector of the node located at the tip of blade number 0 and let $x_{\text{tip}}^{\text{lin}}(2\pi \nu)$ be its Fourier transform. Fig. 9 displays the graphs of $t \mapsto x_{\text{tip}}^3(t)$ and $\nu \mapsto |x_{\text{tip}}^3(2\pi \nu)|$. First of all, it can be seen that the structure returns to its equilibrium state at the end of the simulation. The time response is strongly sensitive to the choice of $\delta t$. The response in the frequency domain displays consequent nonlinear effects, since the structure responds outside the frequency band of excitation $B_e$. The convergence with respect to the choice of $\delta t$ is relatively quick when analyzing the structure in the excitation frequency band. The fundamental frequency of the blisk is also excited through the nonlinearities and it can be seen that this response is strongly over-estimated when choosing $\delta t = 62.5 \times 10^{-6} \text{s}$ and becomes stable from for time steps lower than $\delta t = 15.6 \times 10^{-6} \text{s}$, which is confirmed by the zoom of the nonlinear response in the low-frequency range displayed in Fig. 10. From now on all the computations in the time domain are done taking $\delta t = 15.6 \times 10^{-6} \text{s}$.

### 3.5. Convergence analysis with respect to the order of the reduced-order model

The accuracy of the NL-ROM is investigated with respect to the order $M$ of the reduced-order model. The elastic modes are sorted by increasing order of their eigenfrequencies belonging to a family of modes that are represented in Fig. 4. The load intensity is set to $s_0 = 10 \text{N}$ and the time step is set to $\delta t = 15.6 \times 10^{-6} \text{s}$. Denoting always $u = (u_1, \ldots, u_M)$ as the vector of the $M$ modal coordinates, the convergence function $M \mapsto \text{Conv}_3(M)$ is defined by

$$\text{Conv}_3(M) = \sqrt{\int_{\mathbb{S}} \|u(2\pi \nu; M)\|^2 d\nu},$$

in which $\|u(2\pi \nu; M)\|^2 = \sum_{i=1}^M |u_i(2\pi \nu; M)|^2$ and where the $\mathbb{C}^M$-vector $u(2\pi \nu; M)$ is the Fourier transform of the $\mathbb{R}^M$-valued function $t \mapsto u(t; M)$. The superscript $^{\text{lin}}$ is added for the computation.
Figure 9: Graph of function $t \mapsto x_{3\text{tip}}^0(t)$ representing the nonlinear response at the tip of blade 0 in the transverse direction for different values of $\delta t$ (upper figure). Graph of $\nu \mapsto |x_{3\text{tip}}^{2\pi}(2\pi\nu)|$ in the frequency analysis $\mathbb{F} = [300, 6000]$ Hz.

Figure 10: Zoom of the graph of function $\nu \mapsto |x_{3\text{tip}}^{2\pi}(2\pi\nu)|$ in the very low-frequency range, for different values of $\delta t$.

corresponding to the response of the linearized system. Fig. 11 displays the graphs of functions $M \mapsto \text{Conv}_3^{\text{lin}}(M)$ (upper graph) and $M \mapsto \text{Conv}_3(M)$ (lower graph). It should be noted that for each considered order $M$, the corresponding value of function $\text{Conv}_3(M)$ has been obtained by performing a whole deterministic nonlinear analysis using the NL-ROM parameterized by $M$. As expected, it can be seen that the converged values of both convergence functions differ, that underlines the presence of effects induced by the geometrical nonlinearities. As expected, it can also be seen that the convergence is slower in the nonlinear case. It should also be noted that the nonlinear tuned case yields response levels that are much more lower than the corresponding linearized case, which means that the geometrical nonlinearities have a stiffening effect on the vibrational behavior of the bladed-disk. Note also that the convergence analysis exhibits a maxi-
An analysis of the most contributing generalized coordinates is carried out over $\mathbb{B}$ and presented in Table 3. In the linear case, it is seen that the most contributing generalized coordinates are related to natural eigenfrequencies $\nu_{2,5} = 5091.09 \, \text{Hz}$ and $\nu_{2,4} = 4845.2 \, \text{Hz}$. Moreover there are also two other contributions that are non negligible, that are located in $\mathbb{B}_{r}$, and that are not related to circumferential wave number $h = 2$. This is not theoretically expected since the load has been constructed to only excite circumferential wave number $h = 2$. Nevertheless, in the present case, the forced response is solved in the time domain. The signal is theoretically defined for $t \in \mathbb{R}$ but is numerically truncated, which explains those secondary contributions. In the nonlinear case, all the natural frequencies located in $\mathbb{B}_{r}$ are contributing to the nonlinear response. It should also be noted that the ratios of the generalized coordinates related to natural frequencies $\nu_{2,2} = 2571.5 \, \text{Hz}$ and $\nu_{0,5} = 5266.1 \, \text{Hz}$, that are located outside the excitation frequency band do have a non negligible participation.

Figure 11: Convergence analysis with respect to the order $M$ of the NL-ROM. Graph of function $M \mapsto \text{Conv}_{lin}^{2}(M)$ corresponding to the linearized case (upper graph) and graph of $M \mapsto \text{Conv}_{nl}(M)$ (lower graph).

An analysis of the most contributing generalized coordinates is carried out over $\mathbb{B}$ and presented in Table 3. In the linear case, it is seen that the most contributing generalized coordinates are related to natural eigenfrequencies $\nu_{2,5} = 5091.09 \, \text{Hz}$ and $\nu_{2,4} = 4845.2 \, \text{Hz}$. Moreover there are also two other contributions that are non negligible, that are located in $\mathbb{B}_{r}$, and that are not related to circumferential wave number $h = 2$. This is not theoretically expected since the load has been constructed to only excite circumferential wave number $h = 2$. Nevertheless, in the present case, the forced response is solved in the time domain. The signal is theoretically defined for $t \in \mathbb{R}$ but is numerically truncated, which explains those secondary contributions. In the nonlinear case, all the natural frequencies located in $\mathbb{B}_{r}$ are contributing to the nonlinear response. It should also be noted that the ratios of the generalized coordinates related to natural frequencies $\nu_{2,2} = 2571.5 \, \text{Hz}$ and $\nu_{0,5} = 5266.1 \, \text{Hz}$, that are located outside the excitation frequency band do have a non negligible participation.
3.6. Effects of the geometrical nonlinearities

In order to have a better understanding of the structural behavior of the blisk, it is essential to perform a sensitivity analysis of the nonlinear response with respect to load intensity $s_0$. The computations are carried out with numerical parameters set to $\delta t = 15.6 \times 10^{-6}$ s and $M = 72$. Parameter $s_0$ controls the level of nonlinear effects that can be quantified as follows. A criterion is that the nonlinear response does no longer coincide with the response of the linearized system (small deformations, small displacements) as soon as vibrations appear outside the excitation frequency band $B_e$. As previously, let $u = (u_1, \ldots, u_M)$ be the vector of the $M$ modal coordinates and let $s_0 \mapsto \text{Conv}_4(s_0)$ be the function defined by

$$\text{Conv}_4(s_0) = \frac{\int_{E_1} ||u(2\pi\nu; s_0)||^2 d\nu}{\int_{E} ||u(2\pi\nu; s_0)||^2 d\nu},$$

in which $||u(2\pi\nu; s_0)||^2 = \sum_{i=1}^{M} |u_i(2\pi\nu; s_0)|^2$ and where the $C^M$-vector $u(2\pi\nu; s_0)$ is the Fourier transform of the $\mathbb{R}^M$-valued function $t \mapsto u(t; s_0)$. Such function is equal to unity as long as the linear assumption remains valid. Consequently, there exists a threshold $s_{\min}$ above which geometrical nonlinearities can no longer be neglected. Fig. 12 shows the graph of function $s_0 \mapsto \text{Conv}_4(s_0)$. The threshold value is found to be $s_{\min} = 1 N$.

![Figure 12: Sensitivity analysis with respect to load intensity $s_0$. Graph of function $s_0 \mapsto \text{Conv}_4(s_0)$.](image)

3.7. Convergence analysis with respect to the size $Q$ of the random germ.

As defined in Section 2.4, the global stiffness matrix $[K^{NL}]$ corresponding to a reduced-order model of order $M = 72$ has a size $(P \times P)$ with $P = 72 \times 73 = 5256$. Figure 13 represents the function $j \mapsto [\Lambda^Q]_j$ where the eigenvalues of matrix $[K^{NL}]$ are sorted by decreasing values. One chooses $Q$ so that eigenvalues that are greater than $10^{-6}$ the fundamental one and their corresponding eigenvectors are kept in the reduction so that $Q = 440$. Note that this value defined the length of the random vector used for constructing random matrix $[G(\delta_K)]$. Let be $\text{Conv}_5(Q)$ be the function defined by

$$\text{Conv}_5(Q) = \sqrt{\frac{||\Delta K(Q)||^2}{||K^{NL}]||^2}}.$$

![Figure 13: Convergence analysis with respect to the size $Q$ of the random germ.](image)
It can be shown that $\text{Conv}_5(Q = 440) = 1.98 \times 10^{-6}$ which allows a good representation of the solution to be obtained and which is such that $Q = 440 \ll P = 5256$.

Figure 13: Convergence analysis with respect to the number $Q$ of eigenvectors to be kept in the simulation. Graph of function $j \mapsto [A Q]_{jj}$.

3.8. Convergence analysis with respect to the number of Monte Carlo numerical simulations for the mistuned blisk without intentional detuning

The load intensity is set to $s_0 = 10 \text{N}$ that corresponds to significant nonlinear effects and the numerical parameters are set to $M = 72$ and $\delta t = 15.6 \times 10^{-6} \text{s}$. The pure mistuning (that is to say without intentional detuning) of the blisk is considered through the nonparametric probabilistic approach with a hyperparameter $\delta_K$ set to $\delta_K = 0.1$.

Since the nonparametric probabilistic approach is used for modeling the mistuning, it seems important to precise what is the physical meaning of the choice of hyperparameter $\delta_K = 0.1$ in the pure mistuning case. Figure 14 displays the probability density function of the first three eigenfrequencies with circumferential wave number $h = 0$ using kernel density estimation in order to provide the level of variations of the natural frequencies induced by the pure mistuning when using the nonparametric probabilistic approach. The nonlinear random responses obtained in the pure mistuning case allows for the order of magnitude of the amplification to be estimated, yielding a mean level of amplification of $1.222$, a corresponding standard deviation of $0.164$ and a 98th quantile of $1.629$.

The convergence analysis with respect to the number $n_{\text{sim}}$ of Monte Carlo numerical simulations is investigated. Let $U = (U_1, \ldots, U_M)$ be the random vector of the $M$ modal coordinates on the probability space $(\Theta, T, \mathbb{P})$. Let $\text{Conv}_6(n_{\text{sim}})$ be the function defined by

$$\text{Conv}_6(n_{\text{sim}}) = \sqrt{\frac{1}{n_{\text{sim}}} \sum_{\alpha=1}^{n_{\text{sim}}} \int_B ||U(2\pi \nu; \theta_\alpha)||^2 d\nu},$$

in which, for $\theta_\alpha \in \Theta$, $U(2\pi \nu; \theta_\alpha)$ is the realization of the $\mathbb{C}^M$-valued random variable $U(2\pi \nu)$ such that the $\mathbb{C}^M$-valued function $\nu \mapsto U(2\pi \nu; \theta_\alpha)$ is the Fourier transform of the $\mathbb{R}^M$-valued function $t \mapsto U(t; \theta_\alpha)$. Fig. 15 displays the graph of function $n_{\text{sim}} \mapsto \text{Conv}_6(n_{\text{sim}})$. It is found that a good convergence is obtained from $n_{\text{sim}} = 400$. 

23
Figure 14: Estimation of the probability density function $p_{\nu_0,i}(\nu)$ for $i = \{1, 2, 3\}$ of the first three natural frequencies with circumferential wave number $h = 0$ using kernel density estimation. Corresponding natural frequencies for the tuned case (red line).

Figure 15: Convergence analysis with respect to the number $n_{\text{sim}}$ of realizations for the Monte Carlo numerical simulation of the NL-SROM. Graph of function $n_{\text{sim}} \mapsto \text{Conv}(\text{Conv}(n_{\text{sim}}))$.

3.9. Quantification of the computational costs with regard to the detuning context of the mistuned blisk

These numerical computations are essential (1) to better understand the dynamic behavior of the blisk and (2) to optimize for the best the computational costs while keeping a predictive computational model that ensures a good accuracy on the nonlinear dynamical response. From now on, the load intensity is set to $s_0 = 10 N$ that corresponds to significant nonlinear effects (see Fig. 12). The mistuning level is characterized by a dispersion level $\delta_K = 0.1$ and the numerical parameters are set to $M = 72, \delta t = 15.6 \times 10^{-6} s, n_{\text{sim}} = 500$, and $Q = 440$. It is essential to underline that all these convergence analyses have to be carried out meticulously. The aim of this work concerns the optimization of the detuning of the blisk in presence of mistuning. The computational model of the detuned blisk is constructed from the knowledge of two compatible meshes of two different sector types denoted as 1 and 2. The reference sector 2 is obtained from
sector 1 by decreasing the Young modulus of the blade from $\text{Young}_1 = 2.00 \times 10^{11} \text{ N/m}^2$ to $\text{Young}_2 = 1.80 \times 10^{11} \text{ N/m}^2$.

Let us denote by $n_b_1$ and $n_b_2$ the number of blades of type 1 and type 2 in a detuned configuration. Let $\tilde{n}_c(n_b_1, n_b_2)$ be the number of possible detuned configurations having $n_b_1$ and $n_b_2$ blades of type 1 and 2 respectively. Let $n_c$ be the total number of detuned configurations for all the possible values of $n_b_1$ and $n_b_2$. For the tuned blisk with cyclic symmetry of order $N = 12$, Table 4 gives the number $\tilde{n}_c(n_b_1, n_b_2)$ of detuned configurations as a function of the number $n_b_1$ and $n_b_2$ of blades of type 1 and 2. There are a total number of $n_c = 352$ possible detuned configurations (patterns).

The objective is to find the optimal configuration (pattern) that will reduce for the best the response amplification induced by mistuning. Another objective is to have a complete knowledge of the nonlinear dynamical behavior of all possible detuned configurations in order to constitute a reference data basis. In the present numerical study, all the computations are distributed according to the number $n_{\text{sim}}$ of Monte Carlo realizations and are made on workstations with 1 536 GB RAM and 30 cores (Intel(R) Xeon(R) Platinum 8 168 CPU@2.9Ghz). The generated elapsed time is about 6 hours to perform 1 computation corresponding to the nonlinear analysis of 1 detuned pattern in presence of mistuning, which means that the construction of the full data basis requires an elapsed time of about 88 days of computations.

### 3.10. Choice of the observation

The pure mistuning case corresponds to the usual situation for which the blisk is described with a tuned configuration in presence of mistuning. In that particular case, the deterministic case corresponds to a structure with a perfect cyclic symmetry with order $N$. The usual mistuning analyses, whether it is in a linear or nonlinear context, characterize the mistuning effects by introducing a random amplification factor that is expressed with respect to the deterministic resonance of the structure with perfect cyclic symmetry.

The detuned configuration in presence of mistuning is defined by a given distribution of the blades of type 1 and 2. The detuned configuration number $\ell$ is then represented by a vector $w^{\ell} \in [0, 1]^{n_b}$ whose component $w^{\ell}_j$ is equal to 0 or 1 whether the blade is of type 1 or of type 2. Let us recall that for a given mistuning level, the drastic mistuning effects yield a response amplification with respect to its deterministic counterpart. The objective is to find detuned configurations whose mistuning effects induce less amplification than the one obtained with the tuned configuration in presence of mistuning. The idea is then to define a scalar quantity that is able to quantify the mistuning effects of the detuned configuration with respect to the unavoidable mistuning effects of the tuned configuration.

Let $X^{\ell}(j, 2\pi \nu, \theta_k)$ be the $3n_b$-vector of the realization $\theta_k$ of the $3n_b$-displacement dofs of blade number $j \in \{1, \ldots, n_w\}$ in the frequency domain, taken at frequency $\nu$, and corresponding

<table>

$\tilde{n}_c(n_b_1, n_b_2) = \begin{bmatrix} 1 & 1 & 6 & 19 & 43 & 66 & 80 & 66 & 43 & 19 & 6 & 1 & 1 \end{bmatrix}$
to the detuned configuration number \( \ell \). Let \([t_j]\) be the \((3n_b \times n)\) real matrix that allows for restraining the complex vector of the \(n\) displacement-dofs of the structure to those related to blade number \(j\), we have

\[
X^{\ell}(j, 2\pi \nu_i, \theta_k) = [t_j] [\Phi^{\ell}] U^{\ell}(2\pi \nu_i, \theta_k),
\]

in which \([\Phi^{\ell}] \in \mathbb{R}^{n_b \times n}\) is the matrix of the \(M\) elastic modes for configuration \(\ell\) and where \(U^{\ell}(2\pi \nu_i, \theta_k)\) is the realization \(\theta_k \in \Theta\) of the \(\mathbb{R}^M\)-valued random variable \(U^{\ell}(2\pi \nu_i)\) of the modal coordinates at frequency \(\nu_i\).

For blade number \(j\) of configuration \(\ell\), at frequency \(\nu_i\), and for realization \(\theta_k\), we define the scalar observation \(Y^{\ell}(j, 2\pi \nu_i, \theta_k) = \|X^{\ell}(j, 2\pi \nu_i, \theta_k)\|\). Since the mistuning context requires to consider the resonance of the most responding blade, we define the \(R^+\)-valued random variable \(A^{\ell}\) whose realization \(a^{\ell, k}\) is such that

\[
a^{\ell, k} = \max_j \{\max_i Y^{\ell}(j, 2\pi \nu_i, \theta_k)\}.
\]

We define the associated random variable \(J^{\ell}_{\text{max}}\) whose realization \(j^{\ell}_{\text{max}}\) is such that

\[
j^{\ell}_{\text{max}} = \arg \max_j \{\max_i Y^{\ell}(j, 2\pi \nu_i, \theta_k)\}.
\]

In order to get a robust scalar quantity for characterizing the random nonlinear dynamical behavior of the blisk, an estimate of the maximum extreme value statistics of random variable \(A^{\ell}\) is introduced. It should be noted that, for a fixed \(\ell\)-configuration, the maximum is used so that all realizations are in the confidence domain with the greatest probability. This estimation is constructed as follows. The available number of Monte Carlo numerical simulations is written as \(n_{\text{sim}} = \nu_r \nu_e\) (for \(n_{\text{sim}} = 500, \nu_e = 10\) and \(\nu_r = 50\)). We then define, for \(r \in \{1, \ldots, \nu_r\}\),

\[
a^{\ell, r}_{M} = \max_{k \in \{\nu_e(r-1)+1, \ldots, \nu_e r\}} a^{\ell, k},
\]

in which \(a^{\ell, k}\) is defined by Eq. (36) and we define its mean value, \(a^{\ell, r}_{M}\), such that

\[
a^{\ell, r}_{M} = \frac{1}{\nu_r} \sum_{r=1}^{\nu_r} a^{\ell, r}_{M}.
\]

The observation of the detuned \(\ell\)-configuration with mistuning is then defined as the amplification factor \(q^{\ell}\) with respect to its tuned counterpart with pure mistuning,

\[
q^{\ell} = \frac{a^{\ell}_{M}}{a^{t}_{M}},
\]

in which superscript \(t\) is related to the tuned configuration.

3.11. Some remarks concerning the nonlinear detuning optimization and the linearized detuning optimization

In this paragraph, we investigate the deterministic response of the two tuned configurations with cyclic symmetry with order \(N = 12\). Concerning the tuned configuration with blades of type 1, the natural eigenfrequencies related to the veering with circumferential wave number \(h = 2\) are the double eigenfrequencies \(\nu_{2,4}^{\text{type1}} = 4845.18 \text{ Hz}\) and \(\nu_{2,5}^{\text{type1}} = 5091.09 \text{ Hz}\). Concerning
the tuned configuration with blades of type 2, the natural eigenfrequencies related to the veering with circumferential wave number \( h = 2 \) are the double eigenfrequencies \( \nu_{2,4}^{\text{type}2} = 4596.54 \text{ Hz} \) and \( \nu_{2,5}^{\text{type}1} = 4829.83 \text{ Hz} \). Since the excitation frequency band \( E_c \) is a narrow excitation frequency band chosen as \( E_c = [4700, 5200] \text{ Hz} \), it can be seen that the tuned configuration with 12 blades of type 2 only presents one resonance in \( E_c \). In the linearized case, this means that there will be some detuned configurations for which there will be only one resonance in frequency band of analysis. Let \( y^{\text{type} \alpha}(2\pi \nu_i) \), with \( \alpha = \{1, 2\} \) be the deterministic scalar observation defined similarly to quantity \( Y^\ell(j, 2\pi \nu_i, \theta_k) \). Figure 16 displays the graphs of a zoom of \( \nu \mapsto y^{\text{type} \alpha, \text{lin}}(2\pi \nu_i) \) and \( \nu \mapsto y^{\text{type} \alpha}(2\pi \nu_i) \). It is clearly seen that the nonlinear and linearized response yield very different dynamical behavior due to the external load level for which geometrical nonlinearities occur. Concerning the nonlinear response, the two tuned configurations do exhibit a complex vibrational behavior, with several resonances in and outside the excitation frequency band, which is of interest for considering the nonlinear detuned optimization. Concerning the linearized response, it is seen that the second resonance for the tuned configuration with blades with type 1 has a response level about 5 times smaller than the main resonance. It is also seen that the first resonance for the tuned configuration with blades with type 2 is not captured because the corresponding natural eigenfrequency is localized below the excitation frequency band. For that reason and for the considered case, it does not seems appropriate to consider linearized detuning optimization and to compare it with the nonlinear detuned optimization.

Figure 16: Graph of a zoom of the deterministic response for the nonlinear and linearized response of the tuned configurations with blades of type 1 and of type 2. Graphs of \( \nu \mapsto y^{\text{type}1}(2\pi \nu_i) \) (thick line), \( \nu \mapsto y^{\text{type}1, \text{lin}}(2\pi \nu_i) \) (thin line), \( \nu \mapsto y^{\text{type}2}(2\pi \nu_i) \) (thick dashed line), \( \nu \mapsto y^{\text{type}2, \text{lin}}(2\pi \nu_i) \) (thin dashed line). Excitation frequency band \( E_c \) is represented by the light pink area.

3.12. Detuned configurations that decrease the amplification of the nonlinear response induced by the mistuning

A detuned configuration \( \ell \), which yields a nonlinear mistuned response level that is smaller than the one obtained with the tuned configuration in presence of mistuning, is characterized by \( q^{\ell} < 1 \). Such configuration belongs to the set of optimal detuned configurations. In the detuning process, the tuned configuration \( \mathbf{w}^t = [0 0 0 0 0 0 0 0 0 0 0 0] \) in presence of mistuning is considered and yields amplification \( q^t = 1.0000 \). The detuning is defined around this tuned
configuration. This subset corresponds to \( n_c = 216 \) possible detuned configurations for which the number \( n_{b2} \) of blades of type 2 is less than or equal to \( n_c/2 = 6 \) (see Table 4). However, in this paragraph, we will also consider as possible configurations, the detuned configurations around the other tuned configuration \( w^{c_{t2}} = [1 1 1 1 1 1 1 1 1] \) corresponding to \( n_{b2} > 6 \) and for which the amplification factor is \( q^{c_{t2}} = 1.1252 \). In such a case (see Table 4), there are 136 additional detuned configurations and consequently, the total number of configurations is \( n_c = 352 \), which are randomly ordered. The tuned configuration \( w^{c_{t}} \) corresponds to \( \ell = 49 \).

Fig. 17 shows the graph of \( j \mapsto q^{c_{j}} \) where \( q^{c_{j}} \) are sorted by increasing order for \( n_c = 352 \) (upper graph) and for \( n_c = 216 \) (lower graph). It can be shown that the amplification factor increases from \( q^{c_{49}} = q^{c_{1.04}} = 0.9476 \) until \( q^{c_{9476}} = q^{c_{9}} = 1.1774 \) corresponding to detuned configurations defined by \( w^{c_{1.04}} = [0 0 0 1 0 0 1 0 0 1 0 1] \) and \( w^{c_{9}} = [0 1 0 0 0 1 1 0 0 1 1 1] \). By comparing these two graphs, it is shown that only one improving detuned configuration has a number \( nb_2 \) of blades with type 2 greater than 6. Furthermore, it is seen that the worst detuned configuration \( \ell = 9 \) has a number \( nb_2 \) of blades with type 2 equal to 6. It can also be seen that most of the detuned configurations having a majority of blades with type 2, have a larger amplification factor.

From now on, only detuned configurations corresponding to \( n_c = 216 \) possible detuned configurations for which will be considered. With this new renumbering, it can be seen that there are 14 detuned configurations amongst all the 216 detuned configurations (representing 6.5 % of all the detuned configurations) for which the nonlinear mistuned response has smaller response levels than those obtained with the pure mistuning case. Table 5 summarizes the results obtained with these improving detuned configurations. Note that there is only one configuration that presents a subcyclicity with order \( s = 2 \). The other improving detuned configurations have no particular cyclicity.

Figure 17: Dynamical amplification factor according to detuned configuration. Graph of function $j \mapsto q^{c_j}$ for the $n_c = 352$ detuned configurations (upper graph) and for the $n_c = 216$ detuned configurations with a number of blades with type 2 less than or equal to 6 (lower graph). Subcyclicity order $s$ is given for $s = 2$ (purple square symbol), $s = 3$ (red diamond symbol), $s = 4$ (orange bullet symbol) and $s = 6$ (green triangle symbol).

The tuned configuration $\ell = 211$ with $s = 2$ that has an amplification factor $q^{c_{211}} = 0.9995 \approx 1$ that slightly inhibits the mistuning effects, these subcyclic configurations give rise to an amplification between 5% and 16% with respect to the pure mistuning situation.

3.13. Nonlinear analysis of the mistuned response of the best and the worst detuned configurations

The results are analyzed for the following detuned configurations: the tuned configuration corresponding to the pure mistuning case ($\ell = 49$), the best detuned configuration ($\ell = 104$), and the worst detuned configuration ($\ell = 9$). Fig. 18 displays the graphs of $k \mapsto a^k = A^k(\theta_k)$ for $k = 1, \ldots, n_{\text{sim}}$, which describes the maximum displacement response over the frequency and the blades for each mistuning realization $\theta_k$ of the detuned configurations $\ell \in \{49, 104, 9\}$. By comparing these graphs, it can be seen that the best detuned configuration is characterized
by slightly lower response levels but also by less scattered realizations with respect to the pure mistuned case (left figure). The realizations of the worst detuned configurations (right graph) are clearly more scattered with higher response levels. The distribution of the blades related to these detuned configurations are displayed in Fig. 19. For a given detuned configuration \( \ell \) and a fixed frequency \( \nu \), we introduce the real-valued random variable \( Y_{\max}^\ell (2\pi \nu) \) whose realization \( \theta_k \) is defined by

\[
Y_{\max}^\ell (2\pi \nu, \theta_k) = Y(j_{\max}^{\ell, k}, 2\pi \nu, \theta_k),
\]

in which \( j_{\max}^{\ell, k} \) is defined by Eq. (37). For detuned configurations \( \ell \in \{49, 104, 9\} \), Figs. 20 to 22 display the graphs of the confidence region of the real-valued random function \( \nu \mapsto Y_{\max}^\ell (2\pi \nu) \) for a probability level of 0.98. As expected, it can be seen that the structural displacements are
mainly located in the frequency band of excitation \( B_e \) but that there are also new resonances occurring below the frequency band of excitation \( B_e \) that are induced by the geometrical non-linearities. The amplitudes of these new resonances correspond to the indirect excitation of the first blade modes of the blisk and are of a lower order of magnitude in the present case, probably because the blades are not very slender. Note that this phenomenon has already been observed in previous analyses of nonlinear mistuned blisk for which the blades were slender structures, attached to the disk [36, 47]. Moreover, the phenomenon for which the amplitude of the resonances located below the frequency band of excitation are dominant has been investigated in another context of sloshing in nonlinear fluid structure interaction [60]. Fig. 23 shows a zoom of these confidence regions around the excitation frequency band \( B_e \). It is clearly seen that the pure mistuned blisk have slightly more robust resonances that the one obtained with the detuned configurations in presence of mistuning. But the real interest is to verify that the optimal detuned configuration (middle graph) guarantees that the upper envelope of the confidence region stays below the critical level of response of the pure mistuned response. It is thus observed that the optimal detuned configuration yields a reduction of the maximum amplitude of about 12% with respect to the initial situation that corresponds to the pure mistuning case. Another observation is that the worst detuned configuration yields an amplification of about 11% with respect to the initial situation that corresponds to the pure mistuning case. Note that the resonance involved does not correspond to the main resonance of the pure mistuned system. All these observations allow for assessing the efficiency of the optimization through the output of interest \( q^\ell_c \).

Figure 20: Analysis of the mistuned response for the tuned configuration: graph of the confidence region of \( \nu \mapsto Y_{\text{max}}(2\pi \nu) \) for a probability level of 0.98, corresponding to the pure mistuned configuration \( \ell = 49 \) (purple area). Excitation frequency band \( B_e \) is represented by the light pink area.

3.14. Sensitivity analysis of the nonlinear mistuned response of the best and the worst detuned configurations with respect to the detuning rate and the mistuning rate

It is interesting to perform a sensitivity analysis with respect to the detuning rate for the 3 configurations studied in Section 3.13. The detuning rate is described by the ratio \( r \) defined by

\[
r = 1 - \frac{\text{Young}_2}{\sqrt{\text{Young}_1}}. \tag{39}
\]
It quantifies a ratio for the blade frequency. In this Section, observation \( q^{c,\ell} \) is parameterized as a function of \( r \) and \( \delta_{K} \) and is rewritten as \( q^{c,\ell}(r; \delta_{K}) \). All the optimization process has been carried out for the constant mistuning defined by \( \delta_{K} = 0.1 \) and for a detuning rate \( r = 5.13 \% \) corresponding to blade Young modulus \( \text{Young}_{2} = 1.80 \times 10^{11} \text{N/m}^2 \). The performed sensitivity analysis involves a blade Young modulus \( \text{Young}_{2} \in [1.70, 2.00] \times 10^{11} \text{N/m}^2 \) corresponding to \( r \in [0, 7.8] \% \). The graph \( r \mapsto q^{c,\ell}(r; 0.1) \) is shown in Fig. 24. The purple line describes the pure mistuning case taken as a reference and yielding \( q^{c,\ell}(0, 0.1) = 1 \). As expected, the two investigated detuned configurations \( (\ell = 9 \text{ and } 104) \) tend to converge to the pure mistuned situation as \( r \) goes to zero. Note that the few fluctuations at \( r = 0 \) are caused by the statistical post-processing. The optimal detuned configuration \( \ell = 104 \) further reduces the amplification when the detuning rate is \( r = 4.34 \% \) corresponding to \( \text{Young}_{2} = 1.83 \times 10^{11} \text{N/m}^2 \) yielding
Figure 23: Analysis of the mistuned response for given detuned configurations: for a probability level of 0.98, zoom of the confidence region of $r \mapsto Y_{\text{max}}(2\pi r)$ for the pure mistuned configuration $\ell = 49$ (upper graph), for the best detuned configuration $\ell = 104$ (middle graph), and for the worst detuned configuration $\ell = 9$ (lower graph). Critical level defined by the maximum of the upper envelope corresponding to the pure mistuned situation (red line).

$q^{\ell}(r = 4.34 \%, 0.1) = 0.9394$. Note that this optimum is not necessarily a global optimum since the optimization has been carried out for $r = 5.13 \%$. Moreover, it can also be seen that detuned configuration $\ell = 104$ does not behave monotonically with respect to inhibition or amplification induced by the mistuning. There is a range of detuning rate $r \in [3.30, 6.99] \%$ for which the detuned configuration reduces the amplification induced by the mistuning. But we have to carefully pay attention not to have a detuning rate $r$ smaller than 3.30 %. Note also that the detuned configuration $\ell = 9$ corresponding to the worst detuned configuration in the optimization process increases the amplification induced by the mistuning whatever the detuning rate $r$. Then a sensitivity analysis is performed for these three detuned configurations with respect to the mistuning rate $\delta_K$, which is the hyperparameter that calibrates the uncertainty level in meta-stiffness matrix (See Section 2.4), and which contains both linear and nonlinear stiffness contributions. It is interesting to relate it to physical considerations. For instance, in the pure mistuning case and for a mistuning rate $\delta_K = 0.1$, the confidence region obtained with a probability level of 98% and related to the location of the main resonance is described by a dispersion between $-1.76 \%$ and $+5.59 \%$ around the main resonance. The performed sensitivity analysis involves a mistuning rate from $\delta_K \in [0, 0.24]$. The graph $\delta_K \mapsto q^{\ell}(5.13 \%; \delta_K)$ is shown in Fig. 25. The purple line describes the pure mistuning case taken as a reference and yielding $q^{\text{ref}} = 1$. The detuned configuration $\ell = 9$ never improves the mistuning situation whatever the mistuning rate. Concerning detuned configuration $\ell = 104$ that is optimal for a mistuning rate $\delta_K = 0.1$, there is a threshold value $\delta_K = 0.08$ from which the mistuning amplification effects are inhibited with respect to the pure mistuning situation. A remark concerns the deterministic detuning optimization. It can be seen that neither detuned configurations $\ell = 9$ or $\ell = 104$ allows for inhibiting the mistuning amplification effects as deterministic detuning is considered. Although deterministic optimization
has no meaning because mistuning is an unavoidable phenomenon, it has also been performed and the results show that the optimal solutions are not optimal for the detuning optimization in presence of mistuning. Let $q^c_{\ell,\det}$ be the corresponding quantity of interest related to $q^c_{\ell}$ when considering deterministic detuning (that is to say without mistuning). Table 7 displays the seven optimal deterministic detuned configurations and compares the quantity of interest when detuning optimization is carried out in presence of mistuning. It can be seen that three optimal deterministic detuned configurations belong to the set of the fourteen optimal detuned configurations (in presence of mistuning) but that such detuned configurations are in fact part of the less optimal configurations since the corresponding quantity $q^c_{\ell}$ is close to 1. Table 5 also compares the quantity of interest of the detuning optimization with those obtained when no mistuning is considered. It is interesting to see that such quantity is sensitive to the presence of mistuning. This proves that mistuning cannot be neglected in the detuning optimization process. The most optimal detuned configurations are not optimal solutions when no mistuning is considered in the detuning optimization process.

Table 7: Characteristics of the the improving deterministic detuned configurations without mistuning
Figure 25: Analysis of the sensitivity of mistuned response for given detuned configurations with respect to the mistuning rate $\delta_K$: graph of $\delta_K \mapsto q^{(1.13\%)}(\delta_K)$ for the pure mistuned situation corresponding to $\ell = 49$ (square symbol, purple line), for the best detuned configuration $\ell = 104$ (diamond symbol, green line), and for the worst detuned configuration $\ell = 9$ (circle symbol, orange line). Parameters for optimization process (vertical red line).

4. Optimization of the detuning in presence of mistuning using probabilistic learning on manifolds (PLoM) as a machine learning tool

4.1. Discrete set $N_c$ of a configuration

We consider the detuning of a blisk as the one analyzed in Section 3 having $n_w$ blades and two types of blades that are labelled by integer 0 and 1. A configuration (also called a pattern) of the blisk consists in giving a vector

$$w^c = (w^c_1, \ldots, w^c_{n_w}),$$

in which for $k \in \{1, \ldots, n_w\}$, $w^c_k$ is equal to 0 or to 1. We then define the finite subset $N_c$ of $\mathbb{N}^{n_w}$ such that

$$N_c = \prod_{k=1}^{n_w} \{0, 1\}^{n_w} \subset \mathbb{N}^{n_w},$$

and consequently, $w^c \in N_c$.

4.2. Discrete set $C_c$ of the $n_c$ possible configurations

The total number of all the possible configurations is denoted by $n_c$. As already explained in Section 2.5, $n_c$ can be very large as soon as $n_w$ is large. By excluding the rotations by an integer number of blades, the asymptotic value of $n_c$ is $n_c = (2^{n_w})/n_w$. For instance, if $n_w = 48$, then $n_c = 5.86 \times 10^{12}$. This asymptotic formula includes the configuration with $n_w$ blades of type 0 and the configuration with $n_w$ blades of type 1. If the configurations are restricted to the case for which the number of blades of type 1 is less than or equal to $n_w/2$, then $n_c < (2^{n_w})/n_w$. It will be the case for the configurations of the detuned blisk considered in this section, for which $n_w = 12$ and therefore, $n_c = 216$ (see also Section 3.9).

The finite set $C_c$ of the $n_c$ possible configurations is defined by

$$C_c = \{w^{c,1}, \ldots, w^{c,n_c}\}, \ w^{c,\ell} \in N_c.$$
4.3. Quantity of interest (QoI) computed for a given configuration

For a given configuration $w_{c} \in \mathbb{N}_{c}$, the HFCM is used (see Section 3) for computing the QoI that is the dynamic amplification factor $q_{c} \in \mathbb{R}$ (defined by Eq. (38)) of the detuned disk in presence of random mistuning. Consequently, there exists a mapping $w_{c} \mapsto f_{\text{HFCM}}(w_{c})$ defined on $\mathbb{N}_{c}$ with values in $\mathbb{R}$ such that

$$q_{c} = f_{\text{HFCM}}(w_{c}).$$  \hspace{1cm} (43)

Mapping $f_{\text{HFCM}}$ is completely defined by the set $\{(q^{\ell}, w^{\ell}), \ell = 1, \ldots, n_{c}\}$ of the $n_{c}$ points in $\mathbb{R} \times \mathbb{N}_{c}$ in which $q^{\ell} = f_{\text{HFCM}}(w^{\ell})$ with $w^{\ell} \in C_{c}$.

4.4. Definition of a combinatorial optimization problem on finite set $C_{c}$

Such a combinatorial optimization problem [61, 62, 63] on finite set $C_{c}$ would consist in finding $w_{c,\text{opt}} \in \mathbb{N}_{c}$ such that

$$w_{c,\text{opt}} = \arg \min_{w_{c} \in C_{c}} J_{c}(w_{c}),$$  \hspace{1cm} (44)

in which $w_{c} \mapsto J_{c}(w_{c})$ is chosen for minimizing the dynamic amplification factor defined by Eq. (43), that is to say,

$$J_{c}(w_{c}) = f_{\text{HFCM}}(w_{c}) \quad , \quad w_{c} \in \mathbb{N}_{c}.$$  \hspace{1cm} (45)

(i) The exhaustive search of the combinatorial optimization problem on finite set $C_{c}$, defined by Eqs. (44)-(45), is not tractable and unachievable for large value of $n_{c}$. There are many methods in the literature for solving such a problem: the theory of linear programming [64] including the polynomial-time algorithms [65], integer programming [66] that deals with graph structures [67], the operations research [68], and the computational complexity theory [69]. Certainly, the most popular methods are the branch-and-bound [70], the branch-and-cut [71], the tabu search and greedy [72], and the dynamic programming [73].

(ii) When the numerical cost for the evaluation of $J_{c}(w_{c})$ at any point $w_{c}$ in $C_{c}$ is negligible, then the previous listed methods and algorithms can be used for estimating an optimal solution.

(iii) The specificity of the combinatorial optimization problem under consideration is the high numerical cost of one evaluation $q^{\ell} = f_{\text{HFCM}}(w^{\ell})$ using HFCM. In practice, only $N_{d} \ll n_{c}$ evaluations can be carried out (for instance, $N_{d} = 50$ or 100 while $n_{c}$ can be $10^{12}$). We therefore need to construct a metamodel of $J_{c}$ for computing $J_{c}(w_{c})$ for any $w_{c}$ proposed by the optimization algorithm in order that each evaluation has a negligible numerical cost. We propose to use a machine learning tool for evaluating $J_{c}(w_{c})$ for any $w_{c}$ in $C_{c}$.

4.5. Transforming the combinatorial optimization problem in another one adapted to probabilistic machine learning tools

The combinatorial optimization problem defined by Eqs. (44)-(45) is reformulated in a probabilistic framework, which will be adapted to a machine learning solver in order to limit the number of evaluations using HFCM.

Let $W_{c} = (W_{c,1}, \ldots, W_{c,n_{c}})$ be the $\mathbb{N}_{c}$-valued random variable, defined on a probability space $(\Theta, T, \mathcal{F})$, for which the $n_{c}$ elements $w_{c,1}, \ldots, w_{c,n_{c}}$ of $C_{c}$ are $n_{c}$ independent realizations. Let $Q_{c}$ be the real-valued random variable, defined on $(\Theta, T, \mathcal{F})$ such that

$$Q_{c} = f_{\text{HFCM}}(W_{c}).$$  \hspace{1cm} (46)
Consequently, \( q^{c,\ell} = f_{\text{HFCM}}(w^{c,\ell}) \), \( \ell = 1, \ldots, n_c \) is the set of the \( n_c \) realizations of \( Q^c \). The optimization problem defined by Eqs. (44)-(45) is then replaced by the following one: find \( w^{c,\text{opt}} \in N_c \) such that

\[
    w^{c,\text{opt}} = \arg \min_{w^{c} \in N_c} J_e(w^c),
\]

in which the cost function \( w^{c} \mapsto J_e(w^c) \) is chosen as the conditional mathematical expectation of \( Q^c \) given \( W^c = w^c \),

\[
    J_e(w^c) = E[Q^c | W^c = w^c], \quad w^c \in N_c.
\]

For \( w^{c,\ell} \in C_c \), the conditional random variable \( \{Q^c | W^c = w^{c,\ell}\} \) is equal to the deterministic value \( q^{c,\ell} = f_{\text{HFCM}}(w^{c,\ell}) \). We thus have \( J_e(w^{c,\ell}) = J_e(w^{c,\ell}) \) for \( \ell = 1, \ldots, n_c \), which proves that Eqs. (47)-(48) is a rewriting of Eqs. (44)-(45) for \( w^c \in C_c \). Therefore, this optimization problem is still a combinatorial optimization problem, but \( J_e(w^c) \) will be computed using a probabilistic machine learning tool.

4.6. Definition of the training set \( D_d \) and learned set \( D_{\text{ar}} \) for a probabilistic machine learning tool

Taking into account Section 4.5, we will use a probabilistic machine learning tool for constructing a probabilistic metamodel of cost function \( J_c \) in order to avoid a large number of evaluations of \( J_c(w^c) \) with HFCM for \( w^c \in C_c \).

(i) Training set \( D_d \). The first step consists in generating the training set \( D_d \) by using HFCM. Training set \( D_d \) is made up of \( N_d \) points \( \{q^{c,\ell}, w^{c,\ell}\} \) such that \( q^{c,\ell} = f_{\text{HFCM}}(w^{c,\ell}) \) for \( \ell = 1, \ldots, N_d \) with \( N_d \ll n_c \). This means that the construction of \( D_d \) requires \( N_d \) calls to HFCM, and consequently, \( N_d \) will be small. The training set is therefore, by hypothesis, a small data set (in opposite to a big data set that is generally required for the machine learning algorithms).

(ii) Learned set \( D_{\text{ar}} \). The second step will thus consist in using a machine learning method for generating, from the training set \( D_d \), the learned set \( D_{\text{ar}} \) made up of \( N_{\text{ar}} \) learned realizations \( \{q^{c,\ell}_n, w^{c,\ell}_n\}, \ell = 1, \ldots, N_{\text{ar}} \) of an \( \mathbb{R} \times \mathbb{R}^{n_c} \)-valued random variable \( (Q, W) \) (defined in Section 4.7) without calling HFCM. The number \( N_{\text{ar}} \) of points is chosen sufficiently large (\( N_{\text{ar}} \gg N_d \)) to obtain a converged estimate of the conditional expectation introduced in Eq. (48) for computing \( J_c(w^c) \) for any \( w^c \in C_c \) (see Eq. (42)). So \( D_{\text{ar}} \) can be viewed as a big data set.

4.7. Probabilistic learning on manifolds (PLoM) used as a machine learning tool and approximate combinatorial optimization problem

There are many methods available in the literature for building metamodels. Each method has its own validity assumptions with respect to the input-output dimensions, the complexity of the function to be represented, the number of points in the training set (small or big), the presence or not of uncertainties, a formulation performed in a deterministic or stochastic framework. It is not possible here to propose a review of all these methods, knowing that the use of each requires a precise analysis of its domain of validity, which depends on the hypotheses with which it was constructed. Nevertheless, we refer the reader to [74] for methods based on probability theory and mathematical statistics, including polynomial chaos expansion methodology, to [75, 76, 77, 78, 79, 80] for surrogate based modeling, to [81, 82, 83, 27, 84, 85, 86, 87, 88] for projection-based model reduction, and to [89, 90, 91, 92, 93] for optimization of expensive functions.

The specific difficulty of the problem considered here is the small number of points available in training set \( D_d \) (a few tens or even hundreds for industrial turbomachinery problems) and the
complexity of the function $f_{\text{HFCM}}$. For instance, the very efficient ANN approach [94] cannot be used, \emph{a priori}, for constructing a metamodel of $J$, because $N_d$ is too small. There are methods for sampling underlying distributions on manifolds [95, 96, 97, 98, 99, 100, 101, 102]. Among all these existing methods in machine learning, there is the probabilistic learning method (PLoM), which has specifically been developed for small non-Gaussian data (small value of $N_d$) in arbitrary dimension [103, 104, 105], with the possibility to take into account additional constraints coming from experiments [106] or from nonlinear partial differential equations [107], to construct a polynomial chaos representation of databases on manifolds [77], to construct Bayesian posteriors in high dimension [108], and which has been used for complex optimization problems under uncertainties [93, 109] and challenging applications [110, 111, 112].

(i) \textit{Generating the learned set $D_{\text{ar}}$ with the PLoM method.} We thus propose to use the PLoM method for generating the learned set $D_{\text{ar}}$ from the training set $D_{\text{ar}}$. The PLoM method is adapted to a continuous random variable $X = (Q, W)$, defined on $(\Theta, T, \mathcal{P})$, with values in $\mathbb{R}^n = \mathbb{R} \times \mathbb{R}^n_w$ with $n = 1 + n_w$, while the combinatorial optimization problem defined by Eqs. (47)-(48) is related to the random variable $X^* = (Q^*, W^*)$, in which $Q^* = f_{\text{HFCM}}(W^*)$ (see Eq. (46)) and where $W^*$ is a random variable with values in a finite set $\mathcal{N}_c$. From the training set $D_d = \{(q^d, w^d), \ell = 1, \ldots, N_d\}$, the PLoM method is used for generating the learned set $D_{\text{ar}} = \{(q_{\text{ar}}, w_{\text{ar}}), \ell = 1, \ldots, N_{\text{ar}}\}$.

In order to facilitate the reading of this paper, the reader will find in Section A.1 of Appendix A a summary of the PLoM algorithm. We give this summary, because the proposed algorithm is the assembly of ingredients, which are distributed in three different papers with slightly different notations: basic algorithm of PLoM [103, 104], novel algorithm to estimate the algorithm is the assembly of ingredients, which are distributed in three different papers with slightly different notations: basic algorithm of PLoM [103, 104], novel algorithm to estimate the optimal value of the parameter of the kernel for the calculation of the diffusion-maps basis [105], and taking into account of the normalization constraints [106].

(ii) Approximate combinatorial optimization problem. In order to use the learned set $D_{\text{ar}}$, we introduce the following approximation of the combinatorial optimization problem defined by Eqs. (47)-(48): find $w^{{\text{opt}}}$ in $\mathcal{N}_c$ such that

$$w^{{\text{opt}}} = \arg \min_{w \in \mathcal{N}_c} J_{\text{ar}}(w^c),$$

in which the learned cost function $w^c \mapsto J_{\text{ar}}(w^c)$ is defined by

$$J_{\text{ar}}(w^c) = E[Q | W = w^c], \quad w^c \in \mathcal{N}_c,$$

in which $(Q, W)$ is the random variable with values in $\mathbb{R} \times \mathbb{R}^n_w$, which approximates (for the learning step) random variable $(Q^*, W^*)$ with values in $\mathbb{R} \times \mathcal{N}_c$ and for which the learned realizations are $\{(q_{\text{ar}}, w_{\text{ar}}), \ell = 1, \ldots, N_{\text{ar}}\}$. Since random variable $(Q, W)$ has been defined by its learned realizations, the joint probability density function $p_{Q,W}$ of $(Q, W)$ on $\mathbb{R} \times \mathbb{R}^n_w$ will be constructed by using the multidimensional Gaussian Kernel Estimation (KDE) method with the learned realizations of $D_{\text{ar}}$ (thus this pdf exists by construction, see Section 4.8). With such a hypothesis, the right-hand side of Eq. (50) can be written as

$$E[Q | W = w^c] = \frac{1}{p_W(w^c)} \int_{\mathbb{R}} q \, p_{Q,W}(q, w^c) \, dq,$$

in which $p_W(w^c) = \int_{\mathbb{R}} p_{Q,W}(q, w^c) \, dq$. 

38
(iii) Difficulties induced by the fluctuations (variations) of the cost function. There is still a difficulty with the combinatorial optimization problem defined by Eqs. (49)-(50), induced by the physics of the nonlinear stochastic dynamics of detuned bladed-disks in presence of random mistuning. Function $w' \mapsto f_{\text{HFCM}}(w')$ defined for $w' \in C_c$ has many local minima with very close values (very similar dynamic amplification factor $q' = f_{\text{HFCM}}(w')$ for many different configurations $w'$). This implies that function $w \mapsto J_u(w)$ defined by Eq. (50) and extended on $\mathbb{R}^n_w$, is not convex on $\mathbb{R}^n_w$, and has also many local minima with very close values.

(iv) Reformulation of the combinatorial optimization problem. Taking into account the need to introduce the approximation defined by Eq. (50) to build a metamodel of cost function $J_u$ and taking into account the specificities of its fluctuations (variations) involved by physics, the formulation defined by Eqs. (49)-(50) is not suitable and must be adapted. Estimating a single optimal configuration $w_{\text{opt}}^w$, which yields the smallest dynamic amplification factor, is not sufficiently robust. We therefore propose to reformulate Eq. (49) as follows.

Subset $W^w_{\text{opt}}$ of optimal solutions. Let $n_s \ll n_c$ be an integer that is fixed a priori (chosen as a few units). Let $W^w_{n_s}$ be the subset of $C_c$ made up of the $n_s$ configurations $w^{c_{l_1}}, \ldots, w^{c_{l_{n_s}}}$ in $C_c$ with $\{l_1, \ldots, l_{n_s}\} \subset \{1, \ldots, n_c\}$, which correspond to the $n_s$ first smallest values $J_u(w^{c_{l_1}}), \ldots, J_u(w^{c_{l_{n_s}}})$ of the set $\{J_u(w), w \in C_c\}$. We then have,

$$W^w_{n_s} = \{w^{c_{l_1}}, \ldots, w^{c_{l_{n_s}}}\} \subset C_c,$$

$$J_u(w^{c_{l_1}}) \leq J_u(w^{c_{l_2}}) \leq \ldots \leq J_u(w^{c_{l_{n_s}}}).$$

The subset of optimal solutions of the combinatorial optimization problem is therefore defined as the subset $W^w_{n_s}$ of $C_c$.

(v) Convergence analysis of the subset of optimal solution. Since the conditional mathematical expectation in Eq. (50) will be estimated with the $N_d$ points of the learned set $D_d$, the subset of optimal solution $W^w_{n_s}$ depends on $N_d$ and will be rewritten as $W^w_{n_s}(N_d)$ when necessary. A convergence analysis will be carried out in Section 4.10 with respect to $N_d \gg N_d$.

(vi) Searching a best optimal configuration in the subset $W^w_{n_s}$ of optimal solutions. The hypotheses for constructing the best optimal configuration are the following.

(H1) The number $N_d$ of points in the training set is fixed. This number corresponds to the maximum numerical effort that can be made for performing $N_d$ calls to HFCM. As $N_d$ is assumed to be small, convergence with respect to $N_d$ has no object. Once set $N_d$, we seek to improve the values of the dynamic amplification factors that have been computed with HFCM for constructing the training set.

(H2) Let us assume that $N_d$ and $N_u$ are fixed. As previously explained, taking into account the complexity of the variations of function $f_{\text{HFCM}}$, which is not explicitly known in $C_c$, but only point-by-point using HFCM, it is not possible to demonstrate that subset $W^w_{n_s}(N_u)$ contains an optimal configuration that improves the dynamic amplification factors computed for constructing the training set $D_d$. The only way to do this is to compute again, with HFCM,

$$J_u(w^{c_{l_1}}), \ldots, J_u(w^{c_{l_{n_s}}}),$$

for the $n_s$ configurations of subset $W^w_{n_s}(N_u)$, which have been identified by PLoM (see Eqs. (52)-(53)). Therefore, we define the configuration $w^{c_{l_{n_s};opt}}$ with $\ell_{n_s} \in \{l_1, \ldots, l_{n_s}\}$ as the one that satisfies,

$$w^{c_{l_{n_s};opt}} = \arg \min_{w^{c_{l_j}}, j=1, \ldots, n_s} \{J_u(w^{c_{l_1}}), \ldots, J_u(w^{c_{l_{n_s}}})\}.$$
(H3) Definition of the best optimal configuration. Let \( n_r \) be fixed and let \( \mathbf{w}^{c,\text{opt}} \) be the configuration identified by Eq. (55). If we have
\[
J_c(\mathbf{w}_{\text{wc}}, \ell_{\text{opt}}) < \min_{\ell=1,...,N_d} J_{\text{HFCM}}(\mathbf{w}^c, \ell),
\]
then \( \mathbf{w}^{c,\text{opt}} \) is identified as the optimal configuration in \( \mathcal{W}^{c,\text{opt}}(N_{ar}) \), which is better than all the configurations \( \{\mathbf{w}^c, \ell = 1,...,N_d\} \) used for constructing the training set \( \mathcal{D}_d \).

(H4) If Eq. (56) does not hold, that is to say, a configuration has not be found for improving the knowledge corresponding to the training set, then we can:
(a) Increase the value of \( n_r \) (\( N_d \) remaining fixed at its value). Note that the value of \( n_r \) should be kept small because the number of evaluations with HFCM is \( n_r \).
(b) If (a) is not a success, this means that the value of \( N_d \) is not large enough for obtaining a good learned set \( \mathcal{D}_{ar} \) from the training set \( \mathcal{D}_d \). It is then necessary to increase the value of \( N_d \).
(c) It should be noted that to build the learned set from the training set, the PLoM algorithm is initialized with the points of the training set, which means that the points of the training set belong also to the learned set. Consequently, if the best optimal configuration belongs to the training set, then this optimal configuration will be identified with Eq. (56).

4.8. Estimating the cost function using the learned set

As explained in Section 4.7-(i), the PLoM method allows for generating \( N_{ar} \gg N_d \) realizations \( \{x^e_{ar,\ell}, \ell = 1,...,N_{ar}\} \) with \( x^e_{ar} = (q_{ar}^e, \mathbf{w}_{ar}^e) \) of random variable \( \mathbf{X} = (Q, W) \) with values in \( \mathbb{R} \times \mathbb{R}^n_w \), \( n = 1 + n_w \), without calling HFCM. The classical Gaussian KDE method of the pdf \( x \mapsto p_X(x) \) on \( \mathbb{R}^n \) of random variable \( \mathbf{X} \), with respect to the Lebesgue measure \( dx \), is written \([113, 114, 115, 116]\) as
\[
p_X(x) = \frac{1}{N_{ar}} \sum_{\ell=1}^{N_{ar}} \frac{1}{(2\pi s_{\text{SBX}})^{\frac{n}{2}} \sigma_1...\sigma_n} \times \exp\left(-\frac{1}{2s_{\text{SBX}}} \sum_{k=1}^{n} \frac{(x_k - x_{ar,k})^2}{\sigma_k^2}\right),
\]
in which \( \sigma_k \) is the empirical estimate of the standard deviation of \( X_k \) calculated with \( \{x^e_{ar,\ell}, \ell = 1,...,N_{ar}\} \) and where \( s_{\text{SBX}} \) is the Silverman bandwidth that is written \([117]\) as
\[
s_{\text{SBX}} = \left(\frac{4}{N_{ar}(2 + n)}\right)^{1/(4+n)}.
\]
Since \( \mathbf{W} \) with values in \( \mathbb{R}^n_w \) is a representation of \( \mathbf{W}^c \) with values in the finite set \( \{0,1\}^{n_w} \), a modification of Eq. (57) is proposed as follows.

(i) Random variable \( Q \) is normalized in a random variable \( \tilde{Q} \). Let \( q \) and \( \sigma_Q \) be the empirical mean value and standard deviation of \( Q \) estimated with \( \{q_{ar}^e, \ell = 1,...,N_{ar}\} \). We then have,
\[
Q = \tilde{Q} = (Q - q)/\sigma_Q,
\]
whose realizations of \( \tilde{Q} \) are
\[
\tilde{q}_{ar}^e = (q_{ar}^e - q)/\sigma_Q, \quad \ell \in \{1,...,N_d\},
\]
Consequently, Eq. (50) can be rewritten as

$$J_{\omega}(w^c) = q + \sigma Q E[\hat{Q} | W = w^c], \quad w^c \in \mathcal{N}_c.$$  \hfill (61)

In Eq. (61), the conditional mathematical expectation is written as

$$E[\hat{Q} | W = w^c] = \frac{1}{p_W(w^c)} \int_{\mathbb{R}} \hat{q} p_{\hat{Q}|W}(\hat{q}, w^c) \, d\hat{q},$$  \hfill (62)

in which $p_W(w^c) = \int_{\mathbb{R}} p_{\hat{Q}|W}(\hat{q}, w^c) \, d\hat{q}$ and where $p_{\hat{Q}|W}$ is the pdf on $\mathbb{R} \times \mathbb{R}^n$ of random variable $(\hat{Q}, W)$ with respect to $d\hat{q} \, dw$, whose following construction is directly deduced from Eq. (57).

(ii) The PLoM algorithm that is summarized in Section A.1 of Appendix A is appropriated to the case of a random vector $X$ that belongs to an uncountable set $\mathbb{R}^n$. In the present case, the quantity of interest $Q$ has values in an uncountable set whereas the control variable $W$ is a representation of $W^c$ that takes its values in a finite discrete set. This mixed uncountable - countable case can be approached elegantly with PLoM by taking an adapted value of the Silverman bandwidth of the nonparametric representation of the probability density function of $W$ in order to properly separate the bimodality linked to the two discrete values $\{0\}$ and $\{1\}$. This is done and explained below.

Since $W^c$ is a random variable with values in the finite set $\{0, 1\}^n$ and since the $\mathbb{R}^n$-valued random variable $W$ is a representation of $W^c$, we do not normalize $W$ and we choose its bandwidth as $s_w = c_s s_{\text{raw}}$ for constructing the Gaussian KDE of pdf $p_W$ in order to obtain a possible bimodality centered in 0 and in 1, in which $s_{\text{raw}}$ is the following Silverman bandwidth of $W$,

$$s_{\text{raw}} = \left( \frac{4}{N_w(2 + n_w)} \right)^{1/4 + n_w}.$$  \hfill (63)

The numerical experiments have shown that $c_s = 0.2$ is a good value for obtaining a clear separation (see Fig. 26). Therefore, we have

$$p_W(w) = \frac{1}{N_u} \sum_{u=1}^{N_u} \frac{1}{(s_u \sqrt{2\pi})^{n_u}} \exp\left(-\frac{1}{2s_u^2} \|w - w_u^f\|^2\right),$$  \hfill (64)

in which $\|\|$ is the usual Euclidean norm on $\mathbb{R}^n$.

(iii) Using (i) and (ii), the Gaussian KDE of $p_{\hat{Q}|W}$ is defined as

$$p_{\hat{Q}|W}(\hat{q}, w^c) = \frac{1}{N_u} \sum_{u=1}^{N_u} \frac{1}{s_q \sqrt{2\pi}} \exp\left(-\frac{1}{2s_q^2} (\hat{q} - \bar{q}_{df})^2 \right) \times \frac{1}{(s_u \sqrt{2\pi})^{n_u}} \exp\left(-\frac{1}{2s_u^2} \|w - w_u^f\|^2\right).$$  \hfill (65)

in which $s_q$ is chosen as $s_q = (4/(3N_u))^{1/5}$. From Eqs. (62) and (65), it can be deduced that

$$E[\hat{Q} | W = w^c] = \frac{\sum_{u=1}^{N_u} \bar{q}_{df} \exp\left(-\frac{1}{2s_q^2} \|w - w_u^f\|^2\right)}{\sum_{u=1}^{N_u} \exp\left(-\frac{1}{2s_u^2} \|w - w_u^f\|^2\right)}.$$  \hfill (66)
4.9. Data for the validation of the optimization method based on a probabilistic machine learning tool

In subsections (i)-(iv), there are a few repetitions of results and discussions that have already be given in the previous sections. These small repetitions have voluntary be introduced in order to facilitate the reading of the paper in order to avoid going back and forth in the paper.

(i) Hypothesis and objective for the validation. The number \( n_w \) of blades in the blisk (See Section 3) has deliberately be chosen so that the number \( n_c \) of elements in \( C_c \) (all the possible configurations) is also small in order to build the exact solution of the combinatorial optimization problem defined by Eqs. (44)-(45), in order to be able to validate the proposed approach. For \( n_w = 12 \), the number of all possible configurations for which the blade of type 1 is less than or equal to \( n_w/2 = 6 \) is \( n_c = 216 \). Consequently, 216 calls to HFCM has been carried out for constructing the solution \( w_{c,\text{opt}} \) of Eqs. (44)-(45).

We wish to insist here on the fact that the proposed optimization method has been developed to analyze bladed-disks whose number of blades is such that \( n_c \) leads to a combinatorial optimization problem for which the cost function could only be evaluated with HFCM for \( N_d \) configurations with \( N_d \ll n_c \). In such a case, the construction of the exact solution of Eqs. (44)-(45) is unachievable and therefore, a reference solution would not be available for the validation. For instance, for \( n_w = 24 \), we would have \( n_c \approx 350,000 \), which would require 350,000 call to HFCM, that is unachievable.

(ii) Defining the \( n_c \) configurations of \( C_c \). The \( n_c = 216 \) configurations \( \{w^{\ell,c}, \ell = 1, \ldots, n_c\} \) of \( C_c \) are extracted from the 352 configurations introduced in Section 3.9.

(iii) Computation of the dynamic amplification factor for all the configurations in \( C_c \). In order to construct the exact optimal solution \( w_{c,\text{opt}} \) of the combinatorial optimization problem on finite set \( C_c \), defined by Eqs. (44)-(45), the \( n_c = 216 \) configurations \( \{w^{\ell,c}, \ell = 1, \ldots, n_c\} \) of \( C_c \) are considered and the \( n_c \) dynamic amplification factors \( \{q^{\ell,c} = f_{\text{HFCM}}(w^{\ell,c}), \ell = 1, \ldots, n_c\} \) (see Sections 3.12 and 3.13) have been computed with HFCM. Fig. 27 shows the graph \( \ell \mapsto q^{\ell,c} \) for \( \ell \in \{1, \ldots, n_c\} \).
(1) The configuration \( w^{c,49} \) is the configuration without detuning in presence of random mistuning for which \( w_k^{c,49} = 0 \) for \( k = 1, \ldots, n_w \) and \( q^{c,49} = 1 \).

(2) There are 14 configurations \( \{w^{c,j}, j = 1, \ldots, 14\} \) for which \( q^{c,j} < 1 \). The three smallest values of \( q^{c,j} \) are reached for \( \ell = 104, 123, \) and 166 and are \( q^{c,104} = 0.9476, 0.9529, \) and 0.9537.

(3) It can be deduced that there are 202 configurations for which \( q^{c,j} \) is greater than or equal to 1.

![Figure 27: For the \( n_c = 216 \) configurations of \( C_c \), dynamic amplification factor \( q^{c,j} \) as a function of index \( \ell \in \{1, \ldots, n_c\} \) of configuration \( w^{c,j} \), computed with HFCM.](image)

(iv) Reference Optimal solution of the combinatorial optimization problem defined by Eqs. (44)-(45) on finite set \( C_c \). From the previous paragraph (iii), it can be deduced that the reference optimal solution \( w^{c,104}_{\text{opt}} \) of Eqs. (44)-(45) is \( w^{c,104} = [0 \ 0 \ 1 \ 0 \ 0 \ 1 \ 0 \ 0 \ 1 \ 0 \ 1] \), which is such that \( q^{c,104} = f_{\text{HFCM}}(w^{c,104}) = 0.9476 \).

(v) Defining the subset \( C_{c,q \geq 1} \) of \( C_c \) for constructing the training set. In order to present a validation of the proposed method, which is based on the use of PLoM as a probabilistic learning tool, we consider the most difficult case that consists only of configurations \( w^{c,j} \) for which the dynamic amplification factor \( q^{c,j} \) is greater than or equal to 1. These configurations will constitute a subset \( C_{c,q \geq 1} \) defined by

\[
C_{c,q \geq 1} = \{ (w^{c,j}, j = 1, \ldots, n_{c,q \geq 1}) | q^{c,j} = f_{\text{HFCM}}(w^{c,j}) \geq 1 \}. \tag{67}
\]

Fig. 28 shows the graph \( \ell \mapsto q^{c,j} \) for the \( n_{c,q \geq 1} \) configurations of \( C_{c,q \geq 1} \).

(vi) Defining the training set \( D_d \) for the validation of the machine learning tool. Let \( N_d \) be the number of points in the training set \( D_d \) (see Section 4.6-(i)). For the validation that we propose, 4 values of \( N_d \) are considered. We recall that any convergence analysis with respect to \( N_d \) has no object (see Section 4.7-(vi)-(H1)). The reason for this choice of these four values are the following. The construction of the training set \( D_d \) is then performed as follows. For each considered value of \( N_d \), the first \( N_d \) points of \( C_{c,q \geq 1} \) are selected,

\[
D_d = \{ (q^{c,j}, w^{c,j}), j = 1, \ldots, N_d \} \subset C_{c,q \geq 1}, \tag{68}
\]
For the \( n_{c,q \geq 1} = 202 \) configurations of \( C_{c,q \geq 1} \), graph of the dynamic amplification factor \( q^{(f_j)} = f_{\text{HFCM}}(w^{(f_j)}) \geq 1 \) as a function of index \( j \in \{1, \ldots, n_{c,q \geq 1}\} \) computed with HFCM.

in which \( \{w^{(f_j)}, j = 1, \ldots, N_d\} \) are defined in Section 4.9-(v). The four chosen values of \( N_d \) are 50, 75, 100, and 202.

1) For each one of the two values 50 and 75 of \( N_d \), the prediction of subset \( W_{\text{opt}}^{n_s} \) of \( C_c \) with \( n_s = 6 \) (see Eq. (52)) is carried out and the best solution \( w_{\text{opt}}^{(f_{\ell})} \) is deduced (see Section 4.7-(vi)).

2) The third value \( N_d = 100 \) is then considered in order to compare the corresponding best solution with the one obtained for \( N_d = 75 \).

3) Finally, the last value, \( N_d = n_{c,q \geq 1} = 202 \), has just been considered to check the consistency of the approach proposed for solving the combinatorial optimization problem.

(vii) Values of the parameters of the PLoM algorithm. These values are given in Section A.2 of Appendix A.

4.10. Results and discussion

(i) Convergence analysis of the subset of optimal solutions with respect to the number \( N_{ar} \) of points in the learned set \( D_{ar} \). This convergence analysis with respect to \( N_{ar} \) (see Section 4.6-(ii)) has been defined in Section 4.7-(v) and is carried out for each training set \( D_d \) defined by \( N_d \) points. Let \( \{q_{ar}^{(f_{\ell})}, w_{ar}^{(f_{\ell})}, \ell = 1, \ldots, N_{ar}\} \) be the \( N_{ar} \) points of \( D_{ar} \) generated by PLoM. The criteria for the convergence analysis are the empirical estimates \( \text{conv}_Q(N_{ar}) \) and \( \text{conv}_W(N_{ar}) \) of the mean-square norm of \( Q \) and \( W \),

\[
\text{conv}_Q(N_{ar}) = \left\{ \frac{1}{N_{ar}} \sum_{\ell=1}^{N_{ar}} (q_{ar}^{(f_{\ell})})^2 \right\}^{1/2}, \tag{69}
\]

\[
\text{conv}_W(N_{ar}) = \left\{ \frac{1}{N_{ar}} \sum_{\ell=1}^{N_{ar}} \|w_{ar}^{(f_{\ell})}\|^2 \right\}^{1/2}. \tag{70}
\]

For \( N_d = 50 \), the convergence is obtained for \( N_{ar} = 2 \times 10^7 \), while for \( N_d = 75, 100, \) and 202, for \( N_{ar} = 10^7 \). For illustration and for \( N_d = 75 \), Fig. 29 displays the graph of function \( N_{ar} \mapsto \text{conv}_Q(N_{ar}) \) defined by Eq. (69) while Fig. 30 displays the graph of function \( N_{ar} \mapsto \text{conv}_W(N_{ar}) \) defined by Eq. (70). The graphs of the three other values of \( N_d \) are similar.
(ii) Illustration of the detailed results for \(N_d = 75\) using PLoM. In order to limit the number of figures, we illustrate the results obtained by using PLoM for \(N_d = 75\). Qualitatively, the results for the three other values of \(N_d\) are similar.

(a) Generation of the learned set with PLoM. Figs. 31 and 32 show realizations \(q_{\ell,1}^c\) and \(w_{\ell,1}^{\ell}\) (first component of \(w_{\ell}^c\)) for \(\ell \in \{5240000, \ldots, 5245000\}\) of \(D_{\ar}\) generated by using PLoM (we have presented a zoom in order to avoid a view having an absence of space resolution when the \(10^7\) realizations are plotted). The pdf \(w_1 \mapsto p_{W_1}(w_1)\) of component \(W_1\) of \(W\), estimated using \(\{w_{\ell,1}^c, \ell = 1, \ldots, 10^7\}\) is shown in Fig. 33.

(b) Cost function computed with the learned set. Fig. 34 shows the graph of function \(\ell \mapsto J_{\ar}(w_{\ell}^c)\) for \(\ell \in \{1, \ldots, n_c\}\) (with \(n_c = 216\)) in which \(J_{\ar}(w_{\ell}^c)\) is computed by using Eqs. (61) and (66) with \(N_{\ar} = 10^7\). This graph is superimposed to the graph of function \(\ell \mapsto q_{\ell}^c\) (the reference shown in Fig. 27). It can be seen that the two graphs have similar fluctuations.

(c) Computation of the best optimal solution. For \(n_s = 6\), the indices \(\{\ell_j, j = 1, \ldots, 6\}\) of the 6 configurations \(w_{\ell_j}^c\), which define subset \(W_{n_s}^{opt}\) of optimal solutions (see Eqs. (52) and (53)) are 7, 34, 49, 55, 1, and 166, for which the corresponding values of \(q_{\ell_j}^c\) (see Section 4.9-(iii) and
(d) **Numerical cost.** The numerical cost in terms of Elapsed Time (in seconds) of the analysis performed with a workstation 3072 GB RAM and 110 cores (Intel(R) Xeon(R) Platinium 8280 CPU@2.706 Hz) is the following: 21 607 s for the generation of the learned dataset by the PLoM with constraints and 1 144 s for computing the best optimal solution.

(iii) **Checking the stability and consistency of the proposed methodology and algorithm.** The proposed methodology and algorithm allow for estimating the best optimal solution \( \mathbf{w}^{c, \text{opt}} \) given by Eq. (56), in which \( \mathbf{W}^{c, \text{opt}} \) is constructed using Eqs. (52)-(53), and where \( J_{ar}(\mathbf{w}^{c,l}) \) is computed by Eqs. (61) and (66), in which the learned set \( D_{ar} = \{(q_{ar}^l, \mathbf{w}_{ar}^l), l = 1, \ldots, N_{ar} \} \) is generated using PLoM algorithm from the training set \( D_d \) defined by Eq. (68) for a given value of \( N_d \). In order to check the stability/consistency of the algorithm, we have analyzed the case for which
For $N_d = 75$, pdf $w_1 \mapsto p_{W_1}(w_1)$ of component $W_1$ of $W$, estimated using \{$w_{1,\ell}, \ell = 1, \ldots, 10^7$\} generated by PLoM.

\[ \mathcal{D}_d = C_c \] that is therefore constituted of $N_d = n_c$ points of $C_c$ (see Section 4.9-(iii)). The results are presented in the next paragraph and are good.

(iv) Synthesis of the results obtained as a function of the number $N_d$ of points in the training set $\mathcal{D}_d$. The results obtained with the proposed methodology/algorithm are summarized in Tables 8 and 9 for $n_s = 6$.

1. The best optimal solution obtained for $N_d = 50$ improves the dynamic amplification factors \{$q_{c,\ell}, j = 1, \ldots, 50$\} used in the training set $\mathcal{D}_d$ defined by Eq. (68) for which $q_{c,\ell} \geq 1$, which have been computed with HFCM. However, although $q_{c,\ell}^{opt} = 0.9822 < 1$, it is not a value close to the optimum that is 0.9476. As explained in Section 4.7-(vi)-(H4)-(a) and (b), this solution can possibly be improved by increasing the value of $N_d$ as it can be seen in Table 8.

2. For $N_d = 75$ and, a fortiori, for $N_d = 100$ and 202, the best optimal solutions $q_{c,\ell}^{opt}$ are 0.9529 and 0.9538 that are close to the optimum 0.9476, and which constitute very good predictions.

47

### 5. Conclusion and discussion

We have presented an approach for the optimization of the detuning in presence of random mistuning and geometrical nonlinearities for bladed-disks, based on the use of high-fidelity computational models. This very challenging problem has given rise to very little published work and remains an open subject. The difficulties we have addressed are related to the developments of an efficient computational methodology for reducing the computational cost, to the physics understanding of such stochastic nonlinear dynamical systems, and to the probabilistic formulation of the detuning optimization problem. We have presented a deep computational analysis on a bladed-disk that is representative of industrial turbomachines, in order to understand the role played by the geometrical nonlinearities on the dynamical behavior and to exhibit the consequences on the detuning effects. Several results can be put forward.

A careful convergence analysis with respect to all numerical parameters must be performed to obtain a predictive solution with an optimal computational cost. This is essential for exploring a relatively large number of detuned configurations in the context of the stochastic nonlinear mistuning analysis. It should be noted that the sensitivity analysis with respect to the time step used in the numerical resolution of the nonlinear coupled differential equations is particularly delicate, yielding a fast convergence in the excitation frequency band but a slow convergence in the low-frequency range that is not directly excited by the external loading.

48
Another point of attention concerns the choice of the quantities of interest used in the formulation of the detuning optimization problem from a scalar-valued highly nonlinear cost function. It is found that there is a few number of optimal solutions with respect to the number of possible detuned configurations. It is also proved that the optimization problem is well-posed, yielding to robust optimal detuned configurations that are identified after post-processing analysis as detuned configurations for which the mistuning amplification effects are inhibited with respect to the pure mistuning situation.

The detuning patterns yielding the best optimal detuned configurations and yielding the worst amplification response levels have no particularly structure in terms of number of blades of different types and of blade distribution, which deserve further investigations to understand the complex mechanisms induced by the detuning. As expected, the sub-cyclic detuned configurations that present a cyclic symmetry with a lower cyclic order are sensitive to the mistuning and are not part of the optimal solutions.

For the considered bladed-disk, the sensitivity analysis with respect to the detuning rate or the mistuning rate shows that the detuned configuration yielding the worst case in terms of response amplification remains a wrong detuned configuration whatever the detuning or mistuning rate. There also exists a threshold in terms of detuning rate and mistuning rate from which a detuned configuration belongs to the set of optimal detuned configurations. There is no guarantee that an optimal solution remains optimal when the detuning rate increases too much. Note that the mistuning rate corresponds to the uncertainty level related to the global stiffness matrix with a huge dimension and that the involved magnitude orders are much larger than the uncertainty levels describing the usual frequency mistuning modeling but corresponds in fact to small mistuning levels.

The chosen external load corresponds to a narrow-frequency band of excitation so that the linearized detuning optimization problem has no real interest. It cannot be properly achieved since the natural frequencies of most detuned configurations do not belong to this narrow excitation frequency range and since the structure only can respond in the excitation frequency band. This is to underline that the nonlinear detuned optimization problem is of different nature because of the complex vibratory behavior induced by the geometric nonlinearities that appear themselves as an excitation that spreads the nonlinear response on the whole frequency band of analysis.

Concerning the detuning optimization of bladed-disks in presence of random mistuning, for nonlinear responses regimes involved by geometrical nonlinearities and using high-fidelity computational models, there are no published methods. When the number of detuned configurations is large, we have proposed a reformulation in a probabilistic framework of the combinatorial optimization problem, which is adapted to a probabilistic machine learning tool in order to limit the number of evaluations of the cost function with the high-fidelity computational model. The optimization must be carried out in a probabilistic framework in order to give robustness to the identification of an optimal detuned configuration. It should be noted that the proposed approach is unambiguous as it allows for building a subset of optimal detuned configurations and the search for the optimal solution in this subset is done using the high-fidelity computational model. The methodology proposed has been validated for a 12-bladed-disk structure for which the exact optimal detuned configuration in presence of random mistuning has been identified. A good prediction has been obtained for this very difficult case, which constitutes one validation of the proposed method.
A. Probabilistic learning on manifolds (PLoM), its parameterization and numerical results

A.1. Summary of the PLoM algorithm

The PLoM approach [103, 104, 105] starts from a training set \( \mathcal{D}_0 \) made up of a relatively small number \( N_d \) of points. For the supervised case, it is assumed that the training set is related to an underlying stochastic manifold related to a \( \mathbb{R}^n \)-valued random variable \( X = (Q, W) \) in which \( X, Q \) (quantity of interest), and \( W \) (control parameter) are \( \mathbb{R}^{n_1}, \mathbb{R}^{n_2}, \) and \( \mathbb{R}^{n_3} \)-valued random variables defined on a probability space \((\Theta, T, \mathcal{F})\) with \( n = n_1 + n_2 + n_3 \). Let \( U \) (uncontrolled parameter) be another \( \mathbb{R}^{n_3} \)-valued random variable defined on \((\Theta, T, \mathcal{F})\). Random variable \( Q \) is written as \( Q = f(U, W) = F(W) \) in which the measurable mapping \( f \) is not explicitly known (unknown) and \( F \) is such that \( F = f(U, \cdot) \) is a random mapping. The probability distributions of the vector-valued random variables \( W \) and \( U \) are assumed to be given. The stochastic manifold is defined by the unknown random graph \( \{w, F(w)\} \) for \( w \) belonging to an admissible set \( C_u \), that is the support of the probability distribution of \( W \). With the PLoM construction, its is assumed that this stochastic manifold cannot directly be described. Under these conditions, the non-Gaussian probability measure of \( X \) is concentrated in a region of \( \mathbb{R}^n \) for which the only available information is the cloud of the points of the training set. The PLoM method makes it possible to enrich the available information from the training set. It should also be noted that the estimate of the unknown probability measure of \( X \) is preserved thanks to the use of a diffusion-maps basis that allows to obtain the available information from the training set. It should be noted that the estimate of the unknown probability measure of \( X \) cannot be performed from the training set by using an arbitrary estimator. It must be parameterized in a manner that permits convergence to any probability measure as its number of points in the training set goes towards infinity. The PLoM method therefore does not only consist in generating points that belong to the region in which the measure is concentrated, but also allows these learned points to be realizations of the estimate probability measure with the convergence properties evoked above. The choice of the kernel density estimation method for estimating the probability measure of \( X \) from the training dataset guarantees that this required fundamental property is satisfied [104]. Considering all of these assumptions in the construction and in the methodology of PLoM makes PLoM as a general approach for small datasets for arbitrary non-Gaussian measures. Using the learned set \( \mathcal{D}_0 \), PLoM allows for carrying out any conditional statistics such as \( w \mapsto E(Q|W = w) \) from \( C_u \) in \( \mathbb{R}^{n_3} \), and consequently, to directly construct metamodels in a probabilistic framework.

The training set \( \mathcal{D}_0 \) is made up of the \( N_d \) independent realizations \( \{x^*_j = (q^*_j, w^*_j) \in \mathbb{R}^n = \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, j = 1, \ldots, N_d\} \) of random variable \( X = (Q, W) \). The PLoM method allows for generating the learned set \( \mathcal{D}_0 \) made up of \( N_d \) learned realizations \( \{x^*_\ell = (q^*_\ell, w^*_\ell) \in \mathbb{R}^n, \ell = 1, \ldots, N_d\} \) of random vector \( X \). As soon as the learned set has been constructed, the learned realizations for \( Q \) and \( W \) can be extracted as \( (q^*_\ell, w^*_\ell) = x^*_\ell \) for \( \ell = 1, \ldots, N_d \).

(i) Normalization of the training set. The \( N_d \) independent realizations \( \{x^*_j, j = 1, \ldots, N_d\} \) of \( X \) with values in \( \mathbb{R}^n \) can be represented by the matrix \( [x_d] = [x^*_1 \ldots x^*_N] \) in \( \mathbb{R}^{n \times N} \). Let \( [X] = \)
\[ \mathbf{X} = [\mathbf{x}] + [\varphi] [\mu]^{1/2} [\mathbf{H}], \]  

in which \([\mu]\) is the \((\nu \times \nu)\) diagonal matrix of the \(\nu\) positive eigenvalues of the empirical estimate of the covariance matrix of \(\mathbf{X}\) (computed using \(\mathbf{x}^1, \ldots, \mathbf{x}^N\)). The \((n \times \nu)\) matrix \([\varphi]\) is made up of the associated eigenvectors such that \([\varphi]^T [\varphi] = [\mathbf{I}_n]\). The matrix \([\mathbf{x}]\) in \(\mathbb{H}_n, \mathbb{N}_d\) has identical columns, each one being equal to the empirical estimate \(\mathbf{x} \in \mathbb{R}^n\) of the mean value of random vector \(\mathbf{X}\) (computed using \(\mathbf{x}^1, \ldots, \mathbf{x}^N\)). The columns of \([\mathbf{H}]\) are \(\mathbb{N}_d\) independent copies of \(\mathbf{H}\) with values in \(\mathbb{R}^n\). The realization \([\eta_d] = [\eta^1_d, \ldots, \eta^N_d] \in \mathbb{M}_N, \mathbb{V}_d\) of \([\mathbf{H}]\) (associated with the realization \([\mathbf{x}]\) of \([\mathbf{X}]\)) is computed by \([\eta_d] = [\mu]^{-1/2} [\varphi]^T (\mathbf{x}_d - \mathbf{x})\). The value \(\nu\) is classically calculated in order that the \(L^2\) error function \(\nu \mapsto \text{err}_\nu(\nu)\) defined by 

\[
\text{err}_\nu(\nu) = 1 - \frac{\sum_{d=1}^\nu \mu_d}{\mathbb{E}[\|\mathbf{X}\|^2]},
\]

be smaller that \(\text{err}_{\text{PCA}}\). If \(\nu < n\), then there is a statistical reduction.

(ii) Construction of a reduced-order diffusion-maps basis (ROB). To identify the subset around \(\nu \in \mathbb{N}_d, \mathbb{V}_d\) of the points of the training set are concentrated, the PLoM relies on the diffusion-maps method [118, 119]. This is an algebraic basis of vector space \(\mathbb{H}_n, \mathbb{N}_d\), which is summarized hereinafter. We have to find the value \(m_{\text{opt}} \leq N_d\) of \(m\) and the smallest value \(\varepsilon_{\text{opt}} > 0\) of \(\varepsilon_{\text{err}}\) such that

\[
1 = \lambda_1 > \lambda_2 (\varepsilon_{\text{opt}}) = \ldots = \lambda_{m_{\text{opt}} (\varepsilon_{\text{opt}})} > \lambda_{m_{\text{opt}} + 1 (\varepsilon_{\text{opt}})} \geq \ldots \geq \lambda_{N_d (\varepsilon_{\text{opt}})} > 0 ,
\]

with an amplitude jump equal to an order of magnitude (a factor 10 as demonstrated in [104]) between \(\lambda_{m_{\text{opt}} (\varepsilon_{\text{opt}})}\) and \(\lambda_{m_{\text{opt}} + 1 (\varepsilon_{\text{opt}})}\). This property means that we have to find \(m_{\text{opt}} \leq N_d\) and the smallest positive value \(\varepsilon_{\text{opt}}\) in order (1) to have \(A_2 (\varepsilon_{\text{opt}}) < 1\) (one must not have several
eigenvalues in the neighborhood of 1) and (2) to obtain a plateau for $\lambda_2(\nu_{\text{opt}})$ to $\lambda_{m_{\text{opt}}}(\nu_{\text{opt}})$ with a jump of amplitude 10 between $\lambda_{m_{\text{opt}}}(\nu_{\text{opt}})$ and $\lambda_{m_{\text{opt}}+1}(\nu_{\text{opt}})$. A further in-depth analysis makes it possible to state the following criterion and algorithm to easily estimate $\nu_{\text{opt}}$ and $m_{\text{opt}}$. Let $\nu_{\text{est}} \mapsto \text{Jump}(\nu_{\text{est}})$ be the function on $[0, +\infty[$ defined by

$$\text{Jump}(\nu_{\text{est}}) = \lambda_{m_{\text{opt}}+1}(\nu_{\text{est}})/\lambda_2(\nu_{\text{est}}).$$

The algorithm is the following:
- set the value of $m$ to $m_{\text{opt}} \equiv \nu + 1$;
- identify the smallest possible value $\nu_{\text{opt}}$ of $\nu_{\text{est}}$ in order that $\text{Jump}(\nu_{\text{opt}}) \leq 0.1$ and such that Equation (73) be verified.

Remark concerning the choice of factor 10 for the jump of the eigenvalues. This choice is justified in [104], which gives the mathematical results in support of PLoM (we refer the reader to Theorem 7.8 of this paper and its Lemmas 7.5, 7.6, and 7.7 on which the proof is based). In this paper, it is proven that Eq. (73) must hold for preserving the concentration of the probability measure, which is quantified by the square of the $L^2$-distance (see Eq. (75)), and which is estimated with the $N_d \gg N_d$ learned realizations. Note that there are two important hypotheses in Eq. (73) that must be verified: one is the existence of the plateau for $m \in \{2, \ldots, m_{\text{opt}}\}$ and the other one is the existence of a jump between $m = m_{\text{opt}}$ and $m = m_{\text{opt}} + 1$. In [104], it is proven that the plateau and the jump on the eigenvalues are directly related to the variations of the function $m \mapsto \nu_{\text{opt}}(m)$ (denoted as $m \mapsto \nu_{\text{opt}}(m)$ in [104]), which has to be rapidly decreasing in $m$ in the neighborhood of $m_{\text{opt}}$ by the lower integer values and which has to remain much lower than 1 for $m \geq m_{\text{opt}}$ (see Fig. 1 of [104]). When Eq. (73) holds, then $\nu_{\text{est}}(m) \ll 1$ for $m \geq m_{\text{opt}}$, that is a fundamental property used for proving Theorem 7.8. This property $\nu_{\text{est}}(m) \ll 1$ for $m \geq m_{\text{opt}}$ has been quantified by choosing one order of magnitude for the jump of the eigenvalues.

(iii) Reduced-order representation of random matrices $[H]$ and $[X]$. The diffusion-maps vectors $g^1, \ldots, g^n \in \mathbb{R}^{N_d}$ span a subspace of $\mathbb{R}^{N_d}$ that characterizes, for the optimal values $m_{\text{opt}}$ and $\nu_{\text{est}}$, the local geometry structure of data set $\{\eta^j, j = 1, \ldots, N_d\}$. So the PLoM method introduces the $\mathbb{M}_{N_d,N_d}$-valued random matrix $[H_{\mu}] = [Z_{\mu}] [g_{\mu}]^T$ with $3 \leq m \leq N_d$ corresponding to a data-reduction representation of random matrix $[H]$, in which $[g_{\mu}]$ is the ROB and where $[Z_{\mu}]$ is a $\mathbb{M}_{N_d,N_d}$-valued random matrix for which its probability measure $p_{\mathbb{M}_{N_d,N_d}}([z]) dz$ is explicitly described by Proposition 2 of [104]. The MCMC generator of random matrix $[Z_{\mu}]$ belongs to the class of Hamiltonian Monte Carlo methods, is explicitly described in [103], and is mathematically detailed in Theorem 6.3 of [104]. For generating the learned set, the best probability measure of $[H_{\mu}]$ is obtained for $m = m_{\text{opt}}$ and using the previously defined $[g_{m_{\text{opt}}}]$. For these optimal quantities $m_{\text{opt}}$ and $[g_{m_{\text{opt}}}]$, the generator allows for computing $n_{\text{MC}}$ realizations $[Z_{\mu}]$, $\ell = 1, \ldots, n_{\text{MC}}$ of $[Z_{\mu}]$ and therefore, for deducing the $n_{\text{MC}}$ realizations $[\eta^j]$, $\ell = 1, \ldots, n_{\text{MC}}$ of $[H_{\mu}]$. The reshaping of matrix $[\eta^j] \in \mathbb{M}_{N_d,N_d}$ allows for obtaining $N_d = n_{\text{MC}} \times N_d$ learned realizations $[\eta^j], \ell = 1, \ldots, N_d$ of $H$. These learned realizations allow for estimating converged statistics on $H$ and then on $X$, such as pdf, moments, or conditional expectation of the type $E[\xi(Q)|W = w]$ for $w$ given in $\mathbb{R}^n$ and for any given vector-valued function $\xi$ defined on $\mathbb{R}^n$.

(iv) Quantifying the concentration of the probability measure of random matrix $[H_{\mu_{\text{opt}}}]$. In [104], for $3 \leq m \leq N_d$, we have introduced an $L^2$-distance $d_{\mu}(m)$ of random matrix $[H_{\mu}]$ to matrix $[\eta_{\mu}]$ in order to quantify the concentration of the probability measure of random matrix $[H_{\mu}]$, which
is informed by the training set represented by matrix $[η_d]$. The square of this distance is defined by
\begin{equation}
    d_{H^2}(m) = E[||[H_m] - [η_d]||^2]/||[η_d]||^2.
\end{equation}
Let $M_{opt} = [m_{opt}, m_{opt} + 1, \ldots, N_d]$ in which $m_{opt}$ is the optimal value of $m$ previously defined. Theorem 7.8 of [104] shows that $\min_{m\in M_{opt}} d_{H^2}(m) \leq 1 + m_{opt}/(N_d - 1) < d_{H^2}(N_d)$, which means that the PLoM method, for $m = m_{opt}$ and $[g_{mopt}]$ is a better method than the usual one corresponding to $d_{H^2}(N_d) = 1 + N_d/(N_d - 1) > 2$. Using the $n_{MC}$ realizations $([η^t_d], t = 1, \ldots, n_{MC})$ of $[H_{mopt}]$, we have the estimate $d_{H^2}(m_{opt}) \asymp (1/n_{MC}) \sum_{t=1}^{n_{MC}} [||[g_{t}]||^2]/||[η_d]||^2$.

(v) Generation of learned realizations $[η^t_d, \ell = 1, \ldots, N_d]$ of random vector $H$. The generation of learned realizations $[\hat{Z}_0, \ldots, \hat{Z}_N]$ of random matrix $[\hat{Z}_{mopt}]$ is carried out by using the MCMC generator detailed in [103], which is based on a reduced-order Itô stochastic differential equation (ISDE) that is constructed as the projection on the ROB of the ISDE related to a dissipative Hamiltonian dynamical system for which the invariant measure is the pdf of the following reduced-order ISDE (stochastic nonlinear second-order dissipative Hamiltonian dynamical system), for $t > 0$,
\begin{align*}
    &d[\hat{Z}(t)] = [\Psi(t)] dt , \\
    &d[\Psi(t)] = [\mathcal{L}([\hat{Z}(t)])] dt - \frac{1}{2} f_0 [\Psi(t)] dt \\
    &\quad + \sqrt{f_0} [dW^{mopt}(t)],
\end{align*}
with $[\hat{Z}(0)] = [η_d][a]$ and $[Ψ(0)] = [N][a]$, in which
\begin{align*}
    &[a] = [g_{mopt}] \cdot ([g_{mopt}]^T [g_{mopt}])^{-1} \in \mathbb{R}_{N_d,mopt}.
\end{align*}
\begin{align*}
    &L([u])_{kj} = \frac{1}{p(u)} \nabla_{u} p(u)_{kj}, \\
    &p(u) = \frac{1}{N_d} \sum_{j=1}^{N_d} \exp\{-\frac{1}{2s^2} \left\| \frac{s}{s^v} η^t_j - u_j \right\|^2\},
\end{align*}
\begin{align*}
    &\nabla_{u} p(u) = \frac{1}{s^v s^v} \sum_{j=1}^{N_d} \left( \frac{s}{s^v} η^t_j - u_j \right) \\
    &\quad \times \exp\{-\frac{1}{2s^2} \left\| \frac{s}{s^v} η^t_j - u_j \right\|^2\},
\end{align*}
in which $s^v$ is the modified Silverman bandwidth $s_v$, which has been introduced in [120],
\begin{align*}
    &s_v = \frac{s_v}{\sqrt{s^2_v + \frac{N_d - 1}{N_d}}} , \\
    &s_v = \left\{ \frac{4}{N_d(2 + v)} \right\}^{1/(v+4)}.
\end{align*}
(2) \( \mathbf{W}^{\text{wien}}(t) = [W^{\text{wien}}(t)]_a \) where \([W^{\text{wien}}(t)], t \in \mathbb{R}^+ \) is the \( \mathbb{H}_{N_e} \)-valued normalized Wiener process.

(3) \( \mathcal{N} \) is the \( \mathbb{H}_{N_e} \)-valued normalized Gaussian random matrix that is independent of process \([W^{\text{wien}}]_a \).

(4) The free parameter \( f_0 \), such that \( 0 < f_0 < 4/\bar{s}_e \), allows the dissipation term of the nonlinear second-order dynamical system (dissipative Hamiltonian system) to be controlled in order to kill the transient part induced by the initial conditions. A common value is \( f_0 = 4 \) (note that \( \bar{s}_e < 1 \)).

(5) We then have \( \mathbf{Z}_{\text{lag}} = \lim_{t \to +\infty} \mathbf{Z}(t) \) in probability distribution. The Störmer-Verlet scheme is used for solving the reduced-order ISDE, which allows for generating the learned realizations, \([z_{1,\alpha}^1], \ldots, [z_{\alpha N_e}^{\text{nc}}] \), and then, generating the learned realizations \([\eta_{1,\alpha}^1], \ldots, [\eta_{\alpha N_e}^{\text{nc}}] \) such that \([\eta_{1,\alpha}^i] = [z_{1,\alpha}^i] [\eta_{\alpha N_e}^{\text{nc}}] \).

(6) The learned realizations \( \{ x_{1,\alpha}^i, \ell^c = 1, \ldots, N_{\alpha} \} \) of random vector \( X \) are then calculated (see Eq. (71)) by \( x_{1,\alpha}^i = x + [\varphi][\mu]^{1/2} \eta_{1,\alpha}^i \).

(vi) Constraints on the second-order moments of the components of \( H \) if loss of normalization occurs. In general, the mean value of \( H \) estimated using the \( N_{\alpha} \) learned realizations \( [H_{1,\alpha}^i, \ell^c = 1, \ldots, N_{\alpha}] \), is sufficiently close to zero. Likewise, the estimate of the covariance matrix of \( H \), which must be the identity matrix, is sufficiently close to a diagonal matrix. However, sometimes the diagonal entries of the estimated covariance matrix can be lower than 1 (for instance 0.8). Such a case is application-dependent. Normalization can be recovered by imposing constraints

\[
\{ E([H_i^2]) = 1, k = 1, \ldots, \nu \},
\]

in the algorithm presented in paragraph (v). For that, we use the method and the iterative algorithm presented in [105] (that is based on Sections 5.5 and 5.6 of [106]). The constraints are imposed by using the Kullback-Leibler minimum cross-entropy principle. The resulting optimization problem is formulated using a Lagrange multiplier \( \nu = (\nu_1, \ldots, \nu_\nu) \) associated with the constraints. The optimal solution of the Lagrange multiplier is computed using an efficient iterative algorithm. At each iteration, the MCMC generator detailed in paragraph (v) is used. The constraints are rewritten as

\[
E(\mathbf{h}(\mathbf{H})) = \mathbf{b},
\]

in which the function \( \mathbf{h} = (h_1, \ldots, h_\nu) \) and the vector \( \mathbf{b} = (b_1, \ldots, b_\nu) \) are such that \( h_k(\mathbf{H}) = (H_k)^2 \) and \( b_k = 1 \) for \( k \) in \([1, \ldots, \nu]\). To take into account the constraints in the algorithm of paragraph (v), Eq. (76) is replaced by the following one,

\[
[L_\nu([u])]_{kj} = \frac{1}{p(u^i)} (\nabla_u p(u^i))_{kj} - 2 \nu_k u^i_k.
\]

The iteration algorithm for computing \( \nu^{i+1} \) as a function of \( \nu^i \) is the following,

\[
\nu^{i+1} = \nu^i - \alpha_i [\Gamma'(\nu^i)]^{-1} \Gamma'(\nu^i), \quad i \geq 0,
\]

\[
\nu^0 = 0, \quad \nu^{i+1}, \quad i \geq 0,
\]

(77)
- for \( i \leq i_2 \), \( \alpha_i = \beta_1 + (\beta_2 - \beta_1)(i - 1)/(i_2 - 1) \);
- for \( i > i_2 \), \( \alpha_i = \beta_2 \).

The convergence of the iteration algorithm is controlled by the error function \( i \mapsto \text{err}(i) \) defined by

\[
\text{err}(i) = \frac{\| b - E[h(H_v)] \|}{\| b \|}.
\]  

(78)

At each iteration \( i \), \( E[h(H_v)] \) and \( \text{cov}(h(H_v)) \) are estimated by using the \( N_{ar} \) learned realizations of \( H_{m_{opt}}(v) \) obtained by reshaping the learned realizations.

A.2. Values of the PLoM parameters and results for \( N_d = 75 \)

In order to limit the developments and the number of figures, we only present the case \( N_d = 75 \). The values of the PLoM parameters and the results are similar for the other values of \( N_d \).

(i) PCA of random vector \( X = (Q, W) \). We have \( n_q = 1 \) and \( n_w = 12 \). Consequently, \( X \) is a \( \mathbb{R}^n \)-valued random variable with \( n = 1 + 12 = 13 \). The PCA of \( X \) is constructed using the training set \( D_d \) defined by Eq. (68), with a relative tolerance \( \epsilon_{PCA} = 10^{-6} \). Using Eq. (72) yields \( v = n = 13 \) (so there is no statistical reduction).

(ii) Computation of the diffusion-maps basis. The graph of function \( \varepsilon_{DM} \mapsto \text{Jump}(\varepsilon_{DM}) \) defined by Eq. (74) is shown in Fig. 35 and allows for identifying the optimal value \( \varepsilon_{opt} = 19.6 \) of \( \varepsilon_{DM} \). The function \( \alpha \mapsto \lambda_{\alpha}(\varepsilon_{opt}) \) of the eigenvalues of the transition matrix for \( \varepsilon_{DM} = \varepsilon_{opt} \) is shown in Fig. 36 and shows that the optimal value \( m_{opt} \) of \( m \) is 14. The diffusion-maps basis is made up of the columns of matrix \( [g_{m_{opt}}] \in \mathbb{M}_{\nu,m_{opt}} \).

![Figure 35](image-url)

Figure 35: For \( N_d = 75 \), graph of function \( \varepsilon_{DM} \mapsto \text{Jump}(\varepsilon_{DM}) \) yielding the optimal value \( \varepsilon_{opt} = 19.6 \) of \( \varepsilon_{DM} \).

(iii) Values of the parameters that control the integration scheme of the reduced-order Itô stochastic differential equation. The dissipation coefficient is \( f_0 = 4 \) and the integration step is \( \Delta r = 0.018399 \). The number of realizations of random matrix \( [H] \) with values in \( \mathbb{M}_{\nu,N_d} \) is \( n_{MC} = 133400 \) yielding \( N_{ar} \approx 10^7 \) realizations for the \( \mathbb{R}^\nu \)-valued random variable \( H \).

(iv) Constraints. The constraints \( \{E[H_{ik}^2] = 1, k = 1, \ldots, \nu\} \) are applied for generating the \( N_{ar} \) realizations \( [H_{ik}^\prime, i' = 1, \ldots, N_{ar}] \) of random vector \( H \). The parameters of the relaxation function are \( \beta_1 = 0.01, \beta_2 = 0.2, \) and \( i_2 = 20 \). The graph of the error function \( i \mapsto \text{err}(i) \) defined by Eq. (78) is shown in Fig. 37. The convergence is obtained at iteration \( i = 45 \) for which

55
Figure 36: For $N_d = 75$, graph of function $\alpha \mapsto \lambda_{\alpha}(\epsilon_{\text{opt}})$.

$\text{err}(45) = 4.1 \times 10^{-3}$. Fig. 38 shows the estimation of $\{E[H^2_k]\}$ for $k = 1, \ldots, \nu$ performed with $(\eta_{\alpha}', \ell' = 1, \ldots, N_{\alpha})$ generated in taking into account the constraints. It can be seen that the constraints are satisfied because $E[H^2_k] \approx 1$ for all $k$.

Figure 37: For $N_d = 75$, error function $\text{err}(i)$ as a function of iteration number $i$ of the iterative algorithm for the computation of the Lagrange multipliers.

(v) Quantifying the concentration of the probability measure of random matrix $[H]_{m_{\text{opt}}}$. The use of Eq. (75) yields $d^2_{N_d}(m_{\text{opt}}) = 0.073 \ll 2$, which shows the concentration of the measure is kept.

References

Figure 38: For $N_d = 75$, estimation of $\{E[H^2_k]\}$ for $k = 1, \ldots, \nu$ performed with $\{\eta^{\ell}_d, \ell = 1, \ldots, N_{ar}\}$ generated in taking into account the constraints.
